RADIUM EMANATIONS IN EXOPHTHALMIC GOITER—BLOOD VESSELS OF ADENOMAS OF THYROID*

WALLACE I. TERRY, M.D.
SAN FRANCISCO

The subjects which I desire to offer relate to the thyroid gland. There are many problems connected with goiter which are not yet settled, and if I can add anything to our existing knowledge I shall feel greatly repaid.

FURTHER REPORT ON THE USE OF RADIUM EMANATIONS IN EXOPHTHALMIC GOITER

In THE JOURNAL, a year ago,[1] I made a brief report on the use of radium emanations in the treatment of exophthalmic goiter, based on eleven cases. Since then twenty-two additional cases have been treated by my associates and myself at the University of California Hospital, making a total of thirty-three. Only patients suffering from an extreme degree of hyperthyroidism, due to hyperplasia of the thyroid—the true exophthalmic goiters—have been subjected to this form of treatment, and only with the idea of converting them into better risks for major surgical procedures.

We have endeavored to make the technic of introducing the bare tubes containing radium emanations within the substance of the thyroid gland as simple as intramuscular hypodermic injections. No elaborate skin preparation is made. The operation is done at the office or at the patient's bedside. A local anesthetic is used, and the patient is often permitted to go home within a few hours. For the local anesthetic we prefer to chill the skin at the sites selected with a small cotton sponge saturated with ethyl chlorid. Then the minute capillary tube containing the emanation is introduced into the gland by means of a small caliber, hollow needle, and is pushed into place by a plunger. Usually six emanation tubes, containing a total of from 6 to 10 millicuries, are inserted in the upper, middle and lower thirds of each lobe and through one skin puncture on each side. As the emanations act in all directions, we endeavor to bury the tubes at least half a centimeter in the thyroid, for pathologic changes extend at least that distance from the tube.

Dr. Edwin I. Bartlett has thus described the changes produced by the emanations:

> There is a small area 2 mm. across, pearly white in the center of which can be seen an emanation tube. Microscopically, the area shows for the most part fibrin, with here and there some shadows of old alveoli. Beyond this is a narrow zone of atrophic or degenerating thyroid and increase of connective tissue. Beyond this is compact thyroid tissue with undifferentiated cells, barely formed alveoli or completely formed alveoli. The alveoli are lined by cuboidal or low columnar epithelium, and contain little or no colloid. Many show desquamated cells. Beyond this the picture is that seen in hyperplasia.

This affected area approximates 1 cm. in diameter, but it is possible that a further zone is inactivated than is revealed by the microscope. It would at least seem that in certain of our cases the clinical effect has been more extensive than the pathologic picture would indicate.

Having had considerable experience in operating on goiters which had been treated with roentgen rays, we naturally feared that radium emanations might give rise to annoying adhesions between the thyroid and its surrounding structures, but we were pleased to find that no adhesions were present or that they were minute points where the needles had entered the gland. As the needles are only about 1 mm. in diameter, it is apparent that the adhesions would not be extensive, unless suppuration should follow, which is unlikely, as the tubes containing radium emanations are sterilized, as well as the needles, by boiling. As a matter of fact, the adhesions are less than are found after ligation of an artery.

I realize that radium emanation tubes are available in only a few cities in the United States, but they could be sent by mail or express for 400 or 500 miles. The tubes lose 16 per cent. of their strength each twenty-four hours, so that provision would have to be made to counterbalance the loss during transportation by charging them with sufficient emanations. The total effective action of the emanations in bare tubes is approximately thirty days.

Final results have been obtained in sixteen of the thirty-three cases in which radium emanations were received. Fourteen patients had resections of the thyroid after intervals varying from thirty-two to 114 days after radium. One patient died two days after a bilateral resection from acute hyperthyroidism. Another patient died nine months after resection of both lobes from recurring hyperplasia of the thyroid (substernal) and marked hyperplasia of the thymus and a terminal pneumonia. A third patient died three months after radium, from cirrhosis of the liver. A fourth patient died fifteen days after bilateral resection of the thyroid, from acute yellow atrophy of the liver.

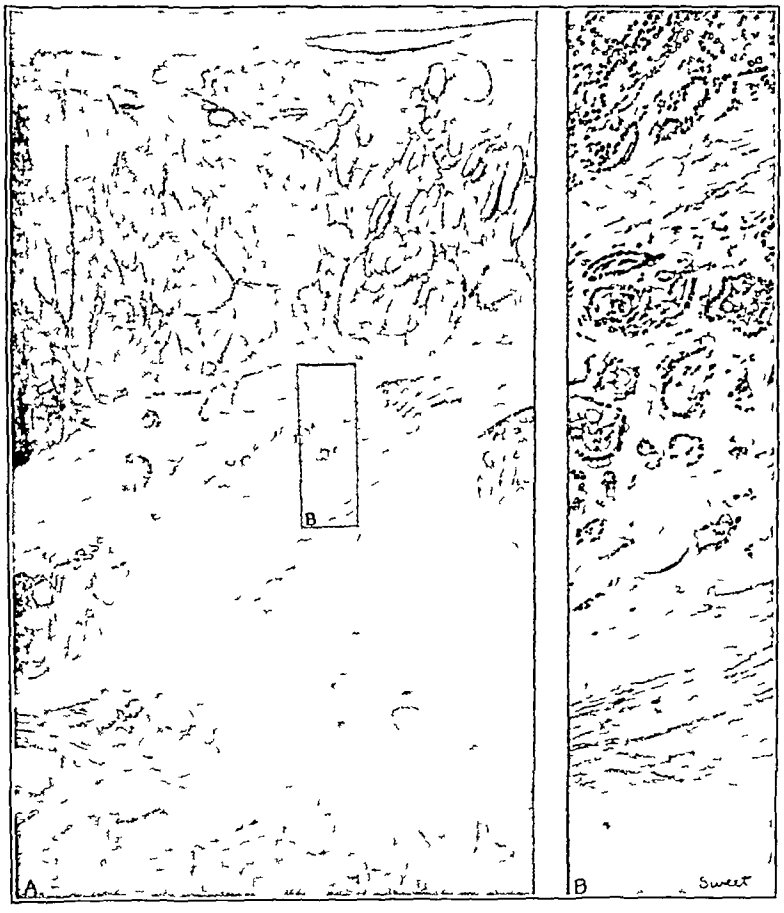
Ten patients are definitely cured after resection. Of these, one had diabetes mellitus, which has apparently disappeared since resection. Another had profound toxemia with jaundice at the time of entrance. She weighed but 67 pounds (31 kg.), and was consid-

* Chairman's address read before the Section on Surgery, General and Abdominal, at the Seventy-Third Annual Session of the American Medical Association, St. Louis, May, 1922.

1. Terry, W. I.: Radium Emanations in the Treatment of Goiter, J. A. M. A. 76: 1821 (June 25) 1921.

ered practically moribund Four tubes, containing 6 millicuries of radium, were put in the thyroid Four months later her weight was 92 pounds (42 kg), and she was considered a sufficiently good risk for resection of the thyroid Since that operation she has steadily gained in all respects Her weight is at her normal of 125 pounds (57 kg), and she is apparently entirely well except for a slight irregularity of the heart

In two cases there has been an apparent cure by radium alone In one the basal metabolic rate was 122 per cent plus before the introduction of eight tubes, containing 5 6 millicuries of radium emanations Two months later his basal metabolic rate was 27 5 per cent plus, and four months after radium it was



A hand lens sketch of radium reaction Center shows necrosis and edges undamaged hyperplastic thyroid Transition from complete necrosis to undamaged tissue is sharp *B* high power view of transitional area

12 9 per cent plus The other patient had a basal metabolic rate of 84 4 per cent plus before five tubes, containing 6 7 millicuries, of radium emanations were given Two months later his basal metabolic rate was 38 per cent plus, and four months after radium it was 5 7 per cent plus He is now working as a stevedore and teamster, and seems entirely recovered

We have not used radium emanations in the treatment of simple colloid goiters or for adenomatous goiters It might be worth a trial in the colloid and simple hypertrophic types, but I think it is distinctly contraindicated in the adenomas for the same reason that the roentgen ray should not be used, viz , the danger of producing atrophy of the thyroid gland proper and consequent hypothyroidism

The conclusions I am willing to draw from our work with radium emanations in goiter are

1 The tubes can be easily introduced into the thyroid gland under local anesthesia

2 The amount of emanations and the number of tubes should vary according to the size of the goiter and the intensity of the symptoms—from 4 to 10 millicuries, contained in from six to eight tubes

3 The emanations are of value in preparing bad risk cases of exophthalmic goiter for further surgical treatment

4 The emanations should not be used in adenomatous goiters

THE BLOOD VESSELS OF ADENOMAS OF THE THYROID

We know that hemorrhages are very likely to occur within adenomas of the thyroid Indeed, the majority of the larger adenomas when sectioned show gross evidence of degeneration, consequent upon hemorrhages within the capsules Such degenerations as calcification, fibrous masses and cysts are probably all the result of effused blood Sudden growth of adenomatous goiters can usually be explained by finding recent blood clots in the adenomas

As it is unusual to find such changes in colloid or hyperplastic goiters, it seemed probable that the explanation might be found through a study of the blood vessels and the blood supply of adenomas At my request, this work was undertaken by Dr G S Delamere, whose training in surgical pathology gave him the necessary qualifications When removing adenomas of the thyroid we took pains to ligate doubly the larger arteries and veins so that most of the blood would remain in the specimens Then the blood was washed out with physiologic sodium chlorid solution, and suspensions of India ink or bismuth subnitrate or camphor-acetone-celloidin mixture were injected into the vessels The technic of the various procedures will be published later, and need not be given here Some of the specimens were stereoscopically roentgenographed so that the vessels could easily be visualized, while others were digested, leaving only the vascular tree Microscopic examinations were made of all except the digested specimens

It was found that the capsular vessels of adenomas freely anastomose, and that many branches penetrate deeply into the substance of the adenomas from these capsular vessels Within the adenomas there is an extremely rich arterial supply, but without any apparent pattern formation The intracapsular vessels also show free anastomoses between them and in all portions of the tumor The vessel walls show certain peculiarities No adventitia as such can be definitely made out, the connective tissue stroma of the gland taking its place The musculature is the most variable element in the walls, occasionally in some of the larger vessels there is only a mere scrap remaining in one por-

The oldest patient examined was 66 years old, and the youngest, 4 More than 50 per cent of the tumors occurred in patients between 41 and 60 The duration of the symptoms ranged from five weeks to four years, the average duration was fourteen months (Table 1)

TABLE 1—AGE OF PATIENTS

Malignant (type not determined)	7
Pathologic examination not made	5
Total	79

Many patients with tumors of the nasopharynx do not come to the clinic because of nose or throat complaint, they are referred for a nasopharyngeal examination from the Section on Ophthalmology, Neurology or General Medicine, because of various symptoms

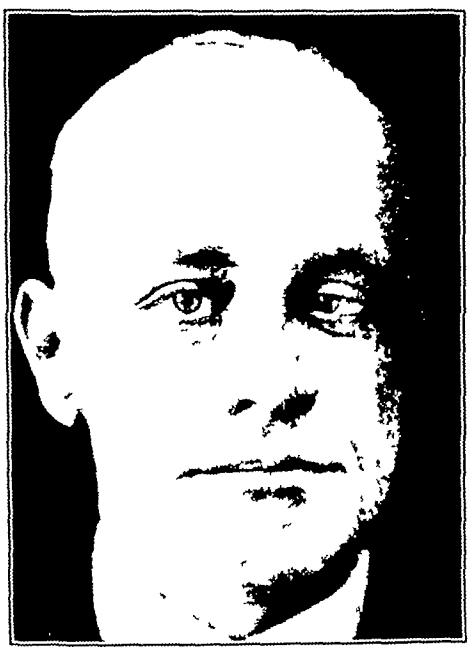

Fig 1 (Case A 321638)—Lymphosarcoma of the left nasopharynx involving the eustachian tube The external rectus had been paralyzed for eleven months A history was given of two years of pain and fullness in the ear The left antrum was irrigated the septum was operated on and tonsillectomy and paracenteses were performed

Often it is only after a careful examination that the tumors are found They are sometimes very small, they are situated laterally in Rosenmuller's fossa, and they usually involve one eustachian tube

The nasopharyngeal examination is made by means of the ordinary No 2 nasopharyngeal mirror Sometimes cocainization and drawing the palate forward by a retractor may be necessary in order to obtain a good view of the nasopharynx I believe the nasopharyngeal mirror gives a much better perspective than can be obtained by special nasopharyngoscopes

In the nasopharyngeal syndrome (Table 3), pain may simulate that in acute conditions of the ear and the patient may have been free from trouble until the acute condition arises The pain may be constant or recurrent, extending over the cheek, the mastoid region, and the frontal and temporal regions, or it may be in the eye It is especially *troublesome when* the patient lies down and is sometimes believed to be due to a tooth Many patients have their teeth removed in the hope of securing relief One patient complained of diplopia and severe frontal headache for six weeks Two patients complained of pain in the occipital region If the tumor involves the gasserian ganglion, the typical pain of trifacial neuralgia may occur and, later, anesthesia and numbness over the distribution of the fifth nerve A small epithelioma of the nasopharynx which had perforated the skull and invaded the ganglion was found in a patient who was referred to the clinic for operation on the ganglion for trifacial neuralgia Shelden[1] asserts that the symptoms and clinical signs of naso-

Fig 2 (Case A 337767)—Lymphosarcoma of the right nasopharynx. The earache started thirteen months before, followed by difficulty in opening the mouth The tonsils and adenoids were removed ten months before, and a mastoid operation was performed nine months before Tuberculous glands of the neck were operated on three months before

TABLE 3—SYMPTOMS

Referable to the jugular foramen	2
Intracranial	11

pharyngeal tumors which have secondarily involved the gasserian ganglion are not distinguishable from symptoms and signs of tumors arising in the cranial cavity and involving the ganglion, and that nasopharyngeal tumors have produced this syndrome almost as often as tumors arising in the skull Many of these patients do not have pain they seek relief from enlarged glands of the neck, tinnitus and deafness, or double vision One patient came for keratosis on one side of the nose and, on routine examination of

1 Shelden W D Tumors Involving the Gasserian Ganglion, J A M A 77 700 705 (Aug 27) 1921

the nasopharynx, a lymphosarcoma was found in Rosenmuller's fossa It had not caused symptoms

Twenty-one of the seventy-nine patients had symptoms referable to the eye at the time of examination The most common complaint was diplopia, and in these cases the external rectus muscle was paralyzed Both sixth nerves may be affected and the upper eyelid ptosed A complete ophthalmoplegia with choked disk may be found, later, there may be optic atrophy

Fig 3 (Case A 305751) —Epithelioma of the right Rosenmuller s fossa involving the gasserian ganglion The eyelids were sewed together for a corneal ulcer There was a history of three years of pain in the right ear and face and an increasing deafness The patient was referred for gasserian ganglion operation

Twenty-nine of the seventy-nine patients complained of the ears, some of gradually increasing deafness with tinnitus or fulness of the ear The onset of this trouble may be acute and a paracentesis may be performed in an attempt to give relief This was done five times in one case of the series Many of the patients had ear treatments, one was treated for six months and had four paracenteses, without the cause of the trouble being discovered, and one had a mastoid operation because of the pain A discharging ear may be a part of the picture Deafness may be bilateral, if both tubes are involved

Only thirty-eight of the seventy-nine patients presented nasal or nasopharyngeal symptoms, such as bleeding or symptoms of nasal obstruction This is significant and it brings out a point that I made in previous papers[2] on this subject, many of these patients are symptomless from the standpoint of the nose and throat, and it is only by careful examination of patients who present part of the syndrome that the tumor is found The tumors do not present the syndrome usually associated with the nasopharynx, such as nasal obstruction, bulging of the palate, and so forth, but often are very small flat growths, situated laterally in Rosenmuller's fossa and involving one tube It is possible that a few tumors that were quite large at the time of the first examination may have originated in the sphenoid

Fifty-one of the seventy-nine patients had enlarged glands of the neck A microscopic diagnosis of endothelioma from the gland removed had been made elsewhere in three cases, in all probability owing to the fact that the primary epithelioma had not been found Metastasis to the glands of the neck is often bilateral, and in the lymphosarcoma group gives a clinical picture of Hodgkin's disease Three of our cases had been thus diagnosed elsewhere The involvement of the glands of the neck may be extensive, with a very small primary growth

Ankylosis of the lower jaw may occur from direct extension of the tumor to the pterygoid muscles Such a condition makes a nasopharyngeal examination more difficult, but when this complaint is associated with pain in the ear or around the head, the possibility of a nasopharyngeal tumor must be eliminated Some patients with this symptom had had their wisdom teeth removed, believing that they might be the cause of the complaint

It may be very difficult to differentiate intracranial and extracranial symptoms, as many of the nerves may be involved extracranially and give the same syndrome as would appear with primary intracranial neoplasm The only possible differentiating point is a unilateral choked disk, and this, of course, is not absolute The growth may penetrate or invade the sella turcica and simulate a pituitary tumor, as occurred in one of the cases reported in a previous paper[3]

The jugular foramen syndrome of Jackson was present in two cases In one case, the ninth, tenth, eleventh and twelfth cranial nerves and the sympathetic nerve were affected, as shown by paralysis of half of the palate, tongue, pharynx and larynx, and the sternocleidomastoid and trapezius muscles There were sensory changes in the pharynx and disturbances of taste over the posterior half of the tongue Enophthalmos, narrowing of the palpebral fissure, and small pupil indicated involvement of the sympathetic nerve In the other case, in which the jugular foramen syndrome was present, all of the cranial nerves on the side were affected except the first and the seventh

Besides the seventy-nine cases of nasopharyngeal tumors, there were four in which a tumor invaded the nasopharynx secondarily Bulging of the lateral wall of the nasopharynx was found, without ulceration One of these tumors presented the jugular foramen syndrome with involvement of the ninth, tenth eleventh and twelfth nerves, but the three others presented pictures similar to the intrinsic nasopharyngeal tumors

Fig 4 (Case A 377033) —Epithelioma of the left nasopharynx with orbital and cervical involvement complete ophthalmoplegia with ptosis of the left upper lid There was a history of two years of pain and deafness The glands of the left side of the neck had been removed fifteen months before

Eighteen of the fifty-one patients in whom the glands of the neck were involved had had operations on the neck without discovery of the primary tumor One patient had had five operations because of recurring involvement of the glands Twenty-three patients had had the tonsils removed after the onset of the com-

Total	74

Observations in these cases demonstrate that many nasopharyngeal tumors are overlooked This may be due to the fact that the patients consulted internists, neurologists, general surgeons or ophthalmologists, and an examination of the nose and throat was not made In most cases, however, the tumor had been overlooked because a careful nasopharyngeal examination had not been made by the laryngologist

The syndrome presented by these tumors is quite typical, and the finding of a small nasopharyngeal tumor will usually clear up the diagnosis in cases in which it had been previously impossible to account for certain symptoms and findings associated with the head (Figs 1-6)

ABSTRACT OF DISCUSSION

DR H W WOLTMAN, Rochester Minn Dr New recently called attention to the relation of malignant tumors of the nasopharynx to other diagnoses Of great importance is the fact that often these patients have no symptoms referable to the nasopharynx From the neurologic standpoint, these cases fall into four fairly well defined groups Pain referred to the side of the head, the ear or the face many times associated with annoying paresthesias, is common This type has been known in the literature as the neuralgic type Then follows the glossopharyngolaryngeal group, patients complaining of dysphagia or recurring attacks of aphonia Finally, there are the cases of mental disturbances, syncopal and epileptiform attacks, and symptoms due to malignant involvement of the distant parts of the nervous system I would like to emphasize the necessity of referring patients having unexplained cranial nerve palsies or symptoms suggesting gasserian ganglion tumor or pituitary tumor to a specialist for a careful examination of the nasopharynx

DR JOSEPH C BECK, Chicago I saw a case of retromaxillary tumor that later became a nasopharyngeal growth of a tuberculous nature in which the jacksonian syndrome was present with other complications The patient had otosclerosis with deafness and he developed a vertical nystagmus I have seen four cases of malignant nasopharyngeal disease in which for a long time the only evidence of involvement of the nasopharynx was a slight bleeding On examining the postnasal space I could not locate any bleeding point However by retracting the palate with a catheter and looking

Fig 6 (Case A 383900) —Epithelioma of the left nasopharynx involving the ninth tenth eleventh and twelfth cranial nerves and the sympathetic nerve (Jackson s syndrome) Enophthalmos small pupil and narrowing of palpebral fissure were noted with paralysis of the left side of the tongue and the sternocleidomastoid and trapezius muscles The left side of the palate and larynx were also paralyzed

directly into the region of the Rosenmüller fossa, I found the bleeding area from which the growth extended I think that while these are nasopharyngeal growths when they come to our attention they probably are retromaxillary tumors as described in Denker s work

DR GORDON B NEW, Rochester, Minn I was much interested in the case Dr Beck reported, but, as the group I am reporting were all malignant cases, it was not included Regarding the retromaxillary group, I have seen several cases with secondary involvement of the nasopharynx from retromaxillary malignancy I believe these are entirely different from those I mention in my paper The group I am reporting are primarily nasopharyngeal tumors and are usually in Rosenmuller's fossa I did not mention treatment because I felt that if I did I would get away from the question of diagnosis We have seen many of these patients who were treated with radium continue well for three or four years, and feel that it is the only treatment that offers relief When surgery has been attempted, most patients have been made worse

MONGOLIAN IDIOCY IN A CHINESE BOY *

I HARRISON TUMPEER, S M, M D
Associate Professor and Head of the Department of Pediatrics Post Graduate Hospital and Medical School Adjunct in Pediatrics Michael Reese Hospital
CHICAGO

The term "mongolian idiocy" is applied to a condition presented by certain children of retarded development manifesting peculiar mental and physical phenomena, the most remarkable of which is the resemblance to the Mongolian facies The mongolian idiot resembles the Mongolian in the oblique palpebral fissure, epicanthal fold, widely placed eyes, flat-bridged, snub nose and expanded ali nasi Brachycephaly is present in both, but the flattening of the occiput is characteristic of the idiot The mongolian idiot differs physically from the Mongolian in the squat hand with tapering fingers, short thumbs and short, incurvated little fingers, the second phalanx of which is shorter than the terminal His hair is not usually black, although it may be straight and is often wiry The face is broad, but it is moon shaped and has no prominent cheek bones He is small in stature and has broad, flat feet There is marked hypermobility of the joints There are chronic infections of the mucous membrane, with affections of the lids, lips, nose and throat The tongue is furrowed and fissured from constant motion It is described as "scrotal" by the French writers There is no blue spot The voice is guttural Changes in the sella turcica have recently been described by Timme [1] The mongolian idiot differs mentally from the Mongolian in his retarded development, marked restlessness and activity, mimicry and indifference to his surroundings In addition, the idiot manifests a fondness for music, exhibits a good sense of rhythm, is very amiable, has a good memory, and is usually contented Sutherland [2] happily states that the "smiling face of the mongolian imbecile suggests the possession of a secret source of joy"

From the time of Langdon Down,[3] who first described mongolian idiocy in 1866, until the present, the cases reported have belonged to the Caucasian race In 1903, Muir [4] concluded from his investigations that this peculiar form of retardation was a matter of the Caucasian race and summarized thus "Mongolism probably exists everywhere, and no white race is exempt"

The case described here illustrates that mongolian idiocy occurs in the Mongolian race, and the Mongolian features of mongolian idiocy are not masked by the Mongolian features of the Mongolian race Indeed, the family of the affected boy testified that "his eyes are more slitlike than those of the other children"

REPORT OF CASE

From the mother it was learned that the child was born at term No instruments were used, and there was no asphyxia The child was breast fed The first tooth appeared at 11 months The child crawled at 13 months, sat up at 14 months, and walked at 2½ years The other children of the family walked at 1 year The first word was spoken at 14 months, and distinct phrases were used at 4 years His speech was never so distinct nor so fluent as that of the other children It was always guttural in tone Nocturnal enuresis stopped at 5 or 6 years, but a tendency remained Later, it was learned that the child was delivered by Dr Effie Lobdell, who gave the information that the labor was *normal* At 6 months, she recognized the condition and prescribed thyroid extract combined with pituitary extract in 2-grain (0 13 gm) doses, three times daily This was continued at varying intervals for three years Dr Lobdell had noted the short, thick fingers and the constant drooling The child was taught to walk in a chair and was found to be very imitative.

Fig 1 —Appearance of patient

The mother stated that he had never had an acute illness, although the drooling and purulent nasal discharge were practically constant

The paternal grandparents died in China at 71 and 74 years of age The maternal grandparents were living in China The family was Cantonese The father was 66 years of age and the mother 38 They were not related to each other All the children were born in the United States There were nine pregnancies There are no other retarded children in the immediate or remote family, and there are no cases of supernumerary digits, such as are sometimes found

In response to a question as to whether they had noted anything peculiar about the boy, his mother and a cousin a

student at the university, volunteered that his eyes were more slitlike than those of the other children, his tongue was larger, and his head was flatter, the other Chinese children of the neighborhood as well as his own brothers and sisters knew that he was different His mother also stated that he was always happy, gave her no trouble, and did not even care if his playthings were taken from him

Examination revealed a moon-faced boy, who looked as if his face had been pushed in (Fig 1) His mouth hung

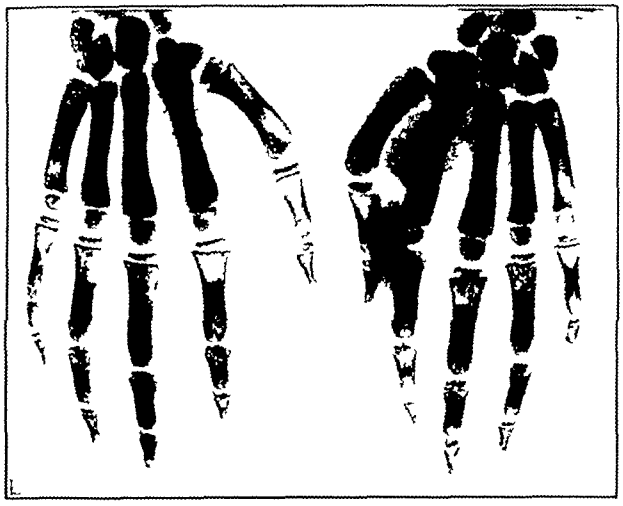

Fig 2—Appearance of hands incurvated little finger shortening of second phalanx of little finger, and normal centers of ossification

open, and a mucopurulent discharge issued from his nostrils The lobules of the ear were adherent, and the bridge of the nose was flattened The eyes were widely spaced, and there was a marked epicanthal fold The teeth were irregular, and many were decayed The pupils reacted to light and accommodation, and were equal The tongue was of the typical "scrotal" variety The tonsils were large and irregular, and the throat was congested There were signs of blepharitis The chest and abdomen were not remarkable There were no signs of the congenital heart lesions which are often described The prepuce was long, and the left testicle was not in the scrotum The reflexes were all active There was marked hypotonia, with hypermobility of the joints, so that the most bizarre attitudes were adopted with ease He assumed the uterine position on lying down The hands were squat, the fingers tapered, the thumbs were stubby, the little fingers were incurvated and did not reach the terminal phalangeal joints of the adjacent fingers There was general adenopathy The scapulae were moderately scaphoid There was no blue spot

The weight was 46½ pounds (21 kg) height, 122 5 cm sitting height, 68 3 cm , occipitofrontal circumferences, 46 6 cm , the anteroposterior diameter, 15 4 cm , biparietal diameter, 14 cm , the arm span 116 5 cm , the interacromial diameter, 26 cm , the intercristal diameter, 19 cm , the chest circumference, 55 cm, and the abdominal circumference 55 cm

Ophthalmoscopic examination revealed no cataract There was marked myopia

The pulse rate was 88, blood pressure, 96 systolic, 70 diastolic

An electrocardiogram revealed a sinus arrythmia a P R interval of 0 14 second, and slight notching of RIII

The basal metabolism with a Tissot apparatus was 9 per cent below the usual, which lies within the normal limits

The Wassermann test on the blood was negative as determined by two different laboratories

Roentgen-ray examination revealed that the second phalanx of the little finger was shorter than the third This finger curved inward (Fig 2) There was also a marked inward curve of the phalanges of the big toe The sella turcica was flattened, and there was a shadow under the anterior clinoid process (Fig 3) There was some separation of the sutures in the vertex of the skull and there were digital impressions, particularly in the frontal region

The mental age of the child was 3 years and 4 months by the Stanford revision of the Binet-Simon scale

CONCLUSIONS

1 This Mongolian child was a mongolian idiot in the generic sense of the word, as proved by the typical findings of the oblique palpebral fissture, epicanthal fold, flattened bridge, widely placed eyes, "pushed in" face, flattened occiput, scrotal tongue, guttural voice, squat hands, Telford Smith[5] finger, stub thumbs, hypotonia, excavation of the sella turcica and other less characteristic findings, such as chronic nasopharyngeal infection, undescended testicle and inward bowing of the phalanges of the great toe There was further proof in the characteristic mental phenomena of restlessness, amiability, mimicry, good memory and mental retardation

2 The most recent finding in mongolian idiocy is here confirmed In twenty-three of his twenty-four cases, Timme found an excavation under the anterior clinoid process and presumably under the olivary process and the optic groove It communicated with the anterior portion of the fossa itself He suggests that this change may explain the stature and lack of sexual development

3 This case speaks against the theory of exhaustion of the generative organs as the etiology of mongolian idiocy, since there were normal children born before and after the patient If the idea of exhaustion be even remotely entertained in this instance, it must be ascribed to the paternal element and not the usually condemned maternal element, since the father was 57 and the mother 29 at the birth of the boy

Fig 3—Appearance of skull shadow communicating with anterior portion of fossa of sella turcica

4 The fact that the basal metabolism rate was not significantly lowered confirms the view that this condition is not primarily, at least, a thyroid hypofunction, and should not therefore be confounded with myxedema This may also explain why striking improvement of these cases by thyroid feeding is not observed

5 Smith Telford Pediatrics 2 315 1892

5 The term idiocy is inaccurate because the mental age reached by those affected is nearly always from 3 to 7 years The condition is more properly mongolian imbecility

CONGENITAL MALFORMATION OF THE HEART

WITH COMPLETE OBLITERATION OF THE PULMONARY ARTERY *

O J RAEDER, M D
PARIS, FRANCE

The question of cardiac malformation is one of those questions supported by contradictory theories which frequently enliven and stimulate productive discussion in what would otherwise be sterile sessions in certain medical research gatherings And so anomalies of the heart have furnished controversial subject matter since the time of Meckel and Cruveilhier

REPORT OF CASE

Baby D, born at term, Nov 20, 1920, with high forceps delivery on account of inertia uteri, died, November 28 The mother, a primipara aged about 40, and father, aged about 45, were in good health The Wassermann test was not made and no history of syphilis was given

The child did not breathe regularly The circulation at times was fairly good, though the color was never a bright baby-pink One hour after birth, the infant became very cyanotic and the breathing was bad Mustard baths and

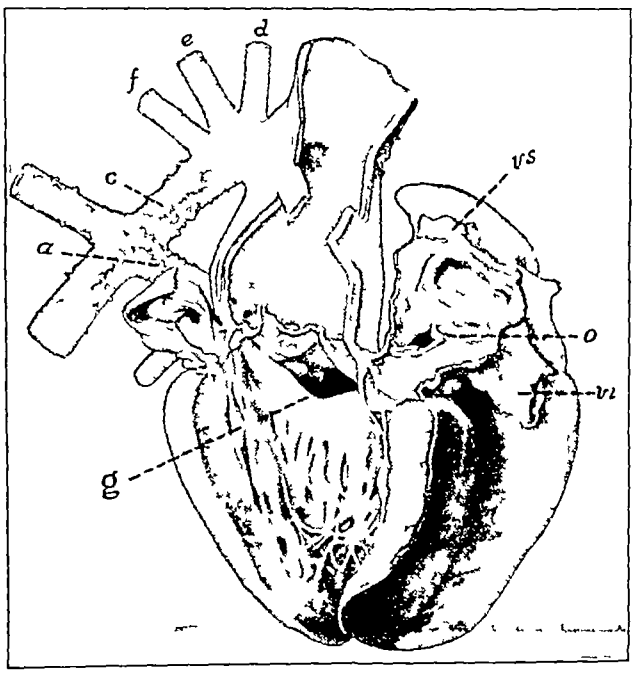

Fig 1—Left side of heart *a* pulmonary artery *c* ductus arteriosus *g* interventricular defect *o* foramen ovale partly covered by membrane

oxygen were administered with prompt result The breathing and color was always much better when the infant was held in the vertical position, whereas if it was held horizontally, there was a more or less marked tendency to cyanosis

On the second day, the child was put to the breast, and though it attempted to nurse on two occasions it did not have sufficient strength It was fed artificially with mother's milk during six days The bowels functioned fairly regularly, with evacuation during the first few days of large quantities of meconium

The temperature was 35 2 C (95 4 F) one hour after birth and ranged between 36 and 38 6 (96 8 and 101 4 F) until the day before death, when it again dropped to 35 4 C (95 8 F) Just before death it was normal

Fig 2—Origin of pulmonary artery in epicardium *a* small button *b* ductus arteriosus *b* tear in ductus arteriosus *d e f* brachiocephalic trunks *m n* branches of pulmonary artery *r* aorta

The infant died on the ninth day, with fairly good color under administration of oxygen, of cardiac failure

Necropsy Report—Abdominal section revealed nothing worthy of note, either from the point of view of pathology or teratologically The pleural cavities were normal The lungs showed no morphologic changes There was hypostatic congestion to a moderate degree, more marked on the left

The pericardial sac contained a slight amount of clear light straw-colored fluid The heart measurements were base to apex, 4 2 cm, breadth, 3 5 cm, thickness, 2 7 cm, left ventricle, wall, from 3 to 4 5 mm, right ventricle, wall, from 2 5 to 3 mm. (hypertrophied), mitral valve, from 26 to 27 mm, aortic valve, 25 mm, tricuspid valve, 35 mm, pulmonary artery origin, 6 mm, left branch, 10 mm, right branch, 9 mm, ductus arteriosus, 11 mm, foramen ovale (diameter), 4 to 5 mm

The aorta was larger than normal The pulmonary artery was very small, tapering down toward its origin from the right ventricle here its wall was thinner and showed a tendency to collapse slightly, like a vein The muscle was firm, the right ventricle hypertrophied On section, the left ventricle opened into the large aorta There was communication with the right ventricle by means of an opening in the interventricular septum There was no outlet from the right ventricle except into the left ventricle at the mouth of the aorta, which was displaced to the right so that its orifice almost straddled the interventricular septum The mitral and tricuspid valves showed small nodules, some of them dark colored, probably the remains of a fetal endocarditis

The aorta was supplied with three efficient valve cusps, the coronary orifices normally placed behind them The arch

* From the obstetric service of Dr Bouffe de St Blaise whom I wish to thank for his kind permission to study this case

of the aorta gave source to a single large branch, which immediately divided into four branches of approximately even caliber The first of these was probably slightly the largest It formed the ductus arteriosus, which was patent and communicated directly with the pulmonary artery, joining the latter at its division in such a manner as to form a cross, the ductus continuing onward, as it were, to form the right pulmonary artery (Fig 1) The three other branches formed the arterial trunks which usually spring directly from the aortic arch

The pulmonary artery from its origin to the point of communication with the ductus arteriosus was small and funnel-shaped, with the apex of the cone in the epicardium of the right ventricular wall When one attempted to pass air by means of a small pipet inserted deeply into this rudimentary vessel, which was patent down to the level of the origin, the bubbles of air always escaped by the ductus arteriosus or by the branches of the pulmonary artery it was impossible to communicate with the right ventricle

SUMMARY

The following anomalies of the heart and vessel trunks were observed

1 Complete obliteration of the pulmonary artery at its origin from the right ventricle
2 Perforation of the interventricular septum
3 Patent ductus arteriosus which functioned from birth until death
4 Hypertrophy of the right ventricle
5 Open foramen ovale
6 Anomaly of the aortic arch and its branches
7 Dilatation of the aorta and displacement of its origin to a position almost directly over the malformed interventricular septum
8 Distinct evidence of a probable fetal endocarditis

COMMENT

At a glance, it is evident that this case does not readily fall into the category of the "tetralogy of Fallot",[1] it more readily fits into the trilogy of Fallot, which is characterized by (*a*) narrowing or total obliteration of the pulmonary artery, (*b*) interventricular communication and (*c*) patent foramen ovale, with, of course, a persistent functioning ductus arteriosus In the present case, there is in addition an unusual abnormality of the arch of the aorta which might furnish material for an interesting study of the embryology of the branchial arches

In discussing the etiology of cardiac anomalies, Prospert,[2] in a recent study of six interesting cases in which necropsy was performed, states that direct heredity as an etiologic factor is very rare Fournier, thirty years ago, laid stress on the role of syphilis as a causal influence Marfan likewise considers syphilis the determining factor in the majority of cases As stated by Prospert,[2] the Wassermann reaction is no criterion here on account of its inconstancy in the newborn According to statistics, in from 60 to 90 per cent of infants with stigmas of syphilis, tests are negative

As mentioned above, opinion has ever been divided between the embryogenic theory formulated by Meckel and the inflammatory theory of Cruveilhier and Lancereaux, the latter of whom went so far as to say, "The teratology of the heart is simply its pathology during uterine life" Apert[3] takes a decided stand against the theory of inflammation Professor Letulle, on the other hand, has persistently emphasized the occurrence of chronic endocarditis in these cases, only recently, he has reopened the question by the report of a case[4] of chronic cardiac inflammation of a very advanced degree, involving the musculature as well as the endocardium Also Professor Vaquez of Paris, even now, staunchly defends the inflammatory theory

Ballantyne[5] says "The heart is almost as perfectly developed at the beginning of the second month of pregnancy as it is a few days before birth therefore, it is extremely difficult to understand how endocarditis supervening between these two dates can produce malformations which are evidently arrests of formative processes anterior to the first of these dates" He quotes Moussons,[6] who makes a nice observation when he says "Malformation predisposes to disease" Laubry and Pezzi,[7] voice the same idea in still more emphatic fashion when they say that pulmonary stenosis with interventricular communication, which is one of the common forms of congenital heart disease, requires an inflammatory process of short duration, springing up always just at that critical few days' period during which the heart is undergoing the development of these parts, namely, the seventh week of embryonic life

In the present case, there is definite evidence of a probable fetal endocarditis (small nodules on the valve cusps of the tricuspid valve) This would seem to lend argument to the theory of fetal inflammation However, the presence of the anisopsia (the right eye was larger than the left), not to mention the curious branching of the vessels of the aortic arch, points with a more reasoning finger to the embryogenic theory The advanced age of the mother is another factor in favor of the latter theory, since it is known from statistics that anomalies are more common in the offspring of primiparous women of an advanced childbearing age

THE DIAGNOSTIC VALUE OF BLOOD FIBRIN DETERMINATIONS

WITH SPECIAL REFERENCE TO DISEASE OF THE LIVER *

JAMES S McLESTER, M D
BIRMINGHAM, ALA

Fibrin, in marked contrast to the other proteins of the blood, varies widely in amount Persons may differ as to the fibrin content of their blood, but for the same person in health the amount is always essentially the same On the other hand, in disease, according to the nature of the morbid process, fibrin values vary to a marked degree

This very labile blood protein is found only in the plasma—not in the cells Its source has been variously stated by investigators to be the intestinal wall, the bone marrow, or the liver Whipple has demonstrated in animals that the production of fibrin is stimulated by slight liver injury, while it is depressed by extensive injury He has reason to believe that this protein is being constantly used up in the body, and his experi-

* Read before the Section on Practice of Medicine at the Seventy Third Annual Session of the American Medical Association St Louis May 1922

ments point to the liver as the sole source of supply One is tempted, therefore, to believe that, when disease of this organ is suspected, a knowledge of the amount of blood fibrin may be of diagnostic value

Since, however, the methods of estimation used in the past either required too much blood or were inaccurate, our knowledge today of the fibrin content of human blood is meager The only comprehensive clinical observations on blood fibrin which I can find are those recently reported by Gram of Copenhagen Certain details of the method devised by him and used in his experiments would lead one to question its absolute accuracy Nevertheless, I have been interested to find how closely his figures tally with mine

A new method which seems to meet the requirements of accuracy and which demands less than 10 c c of blood has just been devised by Foster and Whipple It is readily adaptable to clinical use Briefly the method is this Two c c of oxalated plasma is permitted to clot in a large quantity of physiologic sodium chlorid solution containing a calcium salt The clot, after being thoroughly washed, is dried in a crucible, which is then weighed, ignited, and reweighed The difference in the two weighings tells the amount of fibrin All determinations are made in duplicate

I wish to report a series of observations made by this method on the plasma fibrin of fifteen normal persons and 100 patients, of whom eleven had definite disease of the liver Since the character of one's food seems to influence the amount of his blood fibrin, all specimens for these determinations were obtained before breakfast The figures given are for 100 c c of plasma

For the fifteen normal persons, the fibrin values are nearly alike, varying only from 272 mg to 385 mg, with an average of 333 mg Roughly speaking, normal limits for plasma fibrin seem to be 250 mg and 400 mg

Inflammation and other tissue injury as observed in animals powerfully stimulates fibrinogen production Foster and Whipple call attention to the fact that bacteria play no direct part in this stimulation, since a sterile turpentine abscess is just as effective in increasing blood fibrin as an abscess of bacterial origin Twenty of my patients were acutely ill of various forms of sepsis The plasma fibrin of all of these was increased, varying from 624 mg to 1,120 mg, with an average of 829 mg Four convalescent patients gave lower values, averaging 540 mg, and it is evident that just as soon, for instance, as drainage of an abscess is established the fibrin begins to fall

Related to those with septic inflammatory processes were eight patients with pneumonia The plasma fibrin of these was even more uniformly increased, varying from 726 mg to 1,447 mg, with an average of 1,069 mg Influenzal bronchopneumonia and lobar pneumonia behaved alike as regards fibrinogen stimulation

Since the extent of tissue injury rather than the nature of the infection determines the degree of fibrinogen stimulation, we would expect to find increased fibrin in tuberculosis Such has proved to be the case Among four patients with tuberculous peritonitis, without obvious liver injury, the increased plasma fibrin varied from 621 mg to 938 mg, with an average of 766 mg Three additional patients with pulmonary tuberculosis gave similar figures

In two instances of acute epidemic (lethargic) encephalitis and one of tuberculous meningitis, the plasma fibrin was only a little above normal

One wonders whether the greatly increased fibrin found in the one patient with tetanus—978 mg—could be attributed to increased muscle strain

Two patients with diabetes mellitus and three with peptic ulcer, representing diseases with limited tissue injury, gave only slightly increased fibrin values

The impression was gained that conditions of extreme debility are liable to be accompanied by low plasma fibrin This was exemplified particularly by one case of hookworm infection and another of grave anemia of unknown origin

Two instances of extensive sarcoma were, in spite of the resulting anemia and debility, accompanied by moderately increased fibrin, which leads one to surmise that malignant cell proliferation is a cause of increased fibrinogen production

Four patients with so-called essential hypertension and one with grave uremia showed slightly increased fibrin, averaging 441 mg

Of the heart patients, six with myocardial incompetence, and two with acute endocarditis, all gave moderately elevated figures Others with well compensated myocardial degeneration showed a smaller amount of fibrin

There were three patients with leukemia, two of the myeloid and one of the lymphatic type Two of these patients, presenting both types, had abnormally low fibrin content, 189 mg and 240 mg, while the fibrin of the other was within normal limits It is noteworthy that the two with reduced plasma fibrin content had extensive involvement of the liver, as was evidenced by enlargement One of these was treated by radiotherapy, and, coincident with the improvement in the general health and decrease in the size of the liver, there was increase of the plasma fibrin

There were eleven patients with evident disease of the liver, not including the two with leukemia, of whom I have just spoken Three of these had portal cirrhosis with ascites, and gave moderately low fibrin values, ranging from 222 mg to 373 mg with an average of 301 mg One of these cirrhosis patients also had tuberculous peritonitis, a disease which is usually accompanied by an increase of plasma fibrin, and I think it fair to assume that liver cirrhosis prevented this expected increase Another patient with cirrhosis and ascites had an extremely large liver Unlike those with small livers, his plasma was increased, being 448 mg

The lowest fibrin of the entire series was found in a patient who at necropsy showed extensive tuberculous destruction of the liver He had only 133 mg of fibrin in 100 c c of plasma Here again we assume that the destruction of liver parenchyma prevented the fibrin increase seen in other tuberculous processes

A patient with a freely draining small abscess of the liver, and another with old well-treated syphilis of the liver, both showed increased fibrin, 616 mg and 643 mg

There were four patients with clinical evidence of cancer of the liver The fibrin of three of these varied from 205 mg to 494 mg, with an average of 389 The fourth patient had an enormous liver, sensitive to pressure, which on histologic examination proved to be carcinomatous The very high plasma fibrin found in this last case—1,212 mg and 1,386 mg (two determinations)—was in keeping with the size of the liver, and one is tempted to conclude that prolific growth of tumor cells in the liver, to a certain point at least, stimulates rapid fibrinogen production

SUMMARY

1 The fibrin of normal persons varies approximately from 250 to 400 mg in 100 c c of plasma The same person in health always presents fairly constant values

2 Greatly increased plasma fibrin is seen in all inflammatory tissue reactions of whatever nature

3 Moderately increased fibrin is seen in many other diseases

4 Stimulation of liver parenchyma by inflammation or by tumor growth, or otherwise, seemed to cause increased production of fibrin

5 Great destruction of liver parenchyma decreases fibrin production, the more complete the liver destruction, the lower the blood fibrin

CONCLUSION

Blood fibrin is a very labile body which in its wide fluctuations reflects the nature of the patient's disease It is not unreasonable to expect that further study leading to a more intimate knowledge of the laws which govern fibrinogen production will ultimately give information of direct clinical value

930 South Twentieth Street

PROGRESS IN THE HANDLING OF CHRONIC PEPTIC ULCER

WILLIAM J MAYO, M D
ROCHESTER, MINN

The internist and the surgeon are still far apart in their estimation of the necessity for the surgical treatment of peptic ulcer and of the value of such treatment, but the lines of divergence are converging They are now quite generally agreed that, other things being equal, all patients with chronic mechanical obstruction and those who suffer from repeated hemorrhages or evidences of acute or chronic perforation should be treated surgically They agree also that in all other types of the disease the patient should have as careful medical treatment as circumstances will permit until cure or chronicity is established It goes without saying that recent ulcers should be treated medically The surgeon sees patients whom medical treatment has failed to cure permanently, and he is, perhaps, less enthusiastic in his prognosis under such treatment than the internist who has relieved patients, greatly to their comfort and enthusiasm Patients the internist fails to relieve slip quietly into other hands and later may come to operation Not infrequently the surgeon sees patients who have been "cured" by a number of internists, as they in good faith believe On the other hand, the internist sees a considerable number of patients who have so completely failed to obtain relief from surgical treatment as to give him a healthy suspicion of its value

The natural history of the development of peptic ulcer is interesting The patient suffering from ulcer has spells of more or less severe symptoms, followed with treatment or without treatment, by periods of marked relief, lasting perhaps for months or years Gradually, however, the periods of improvement diminish, and the exacerbations become more frequent and prolonged, until permanent crippling is manifest The amount of disability depends on the location, depth and attachment of the ulcer, factors which greatly influence the severity of symptoms, especially as they relate to pain and interference with nutrition It is sometimes a little difficult for the uninitiated to see the difference between the spontaneous improvement which is a definite feature of the natural course of the disease and the improvement brought about by medical treatment However, any fair-minded observer will admit readily that careful medical management usually results in great improvement and amelioration of the symptoms, and that, if such management can be continued, the improvement may be prolonged, and even become permanent

THE FINANCIAL QUESTION

The successful medical management of peptic ulcer presupposes the hospitalization of the patient for a number of weeks under a regimen which, in order to be successful, must be rigid and prolonged, and carried on by the patient afterward Unfortunately, only a small number of patients with peptic ulcer are financially able to make a pet of an ulcer More than 90 per cent of those coming to us are wage earners who cannot afford the time and care that are necessary for medical cure At more or less frequent intervals, their wage earning capacity has been interfered with seriously by undernutrition, pain, and disability Their diet cannot be controlled, as their social condition compels them to eat such food as they are able to obtain and pay for To prescribe a specific diet for a laboring man working for wages on a farm or in a factory, or even for one in his own home under present day household conditions, is about as reasonable as advice given in the past to a poor man with tuberculosis, and with a family to support, "go to Colorado or Arizona and do nothing for two years" As a result of these practical considerations, prolonged medical treatment of peptic ulcer is out of the question for the large majority of patients Nearly all such patients have been treated medically, but, under existing circumstances, ineffectually They have little desire to undertake further medical treatment and readily accept surgery Only the minority are willing and financially able to submit to proper medical management That medical treatment, under most favorable circumstances, often fails to cure permanently, must be conceded by even the most enthusiastic advocates Enough has been said to indicate that patients with peptic ulcer cannot be treated as a group Each case must be considered individually, and, when it is reasonably possible, careful medical management of the ulcer should be given a thorough trial before operation is recommended Following operation, the after-care of the patient should be conducted by the internist Possibly educational propaganda may be instituted for the benefit of the patient with peptic ulcer, as has been done for the patient with diabetes

In connection with our care of these patients, we are establishing a diet kitchen, where they will be taught how to prepare their food properly and how to live

RESULTS OF TREATMENT

It is not necessarily the fault of the internist that medical treatment fails so often He knows that in many cases nonsurgical treatment has not had a fair chance The sins of the internist are omissions, those of the surgeon, commissions, shortcomings in the surgical field are more disastrous to the patient

To express it in the form of an Hibernicism, the most frequent cause of surgical failure in such cases is to operate for peptic ulcer when there is no ulcer The patient may have been treated medically for a long time without cure Prolonged medical treatment is sometimes accepted by the surgeon, in his innocent respect for the previous diagnosis, as one of the indications for operation, and an unnecessary gastro-enterostomy is performed, which leads surgery into disrepute At the Mayo Clinic we have removed several hundred unnecessary gastro-enterostomies that had been made in good faith and bad judgment, fourteen of them were our own early cases Such instances are solace to the medical man who holds them up as evidence of the failure of surgery to cure peptic ulcer instead of failure to cure a wrong diagnosis

Another occasional cause of dissatisfaction with the surgical treatment of chronic peptic ulcer is the curious obsession, apparently common to the patient, his medical adviser, and his surgeon, that if the first operation is not successful, surgery has shot its only arrow We have recognized the fact that medical treatment may be repeated, but we have been slow to see that surgical operation may be repeated, provided it has a definite object It has been shown that in more than 90 per cent of duodenal ulcers and more than 80 per cent of gastric ulcers satisfactory results are obtained by single operations Some of these ulcers, however, have deep craters, and when these involve the pancreas, with fixation of the gastric or duodenal wall, pain may continue or hemorrhages may recur If 90 per cent of patients with duodenal ulcers get well without excision of the ulcer, shall the entire 100 per cent be subjected to radical operation, with increased risk, in order to protect the 10 per cent from secondary operation? Increasing experience enables one to prognosticate, with a fair degree of accuracy, which of the ulcers of the duodenum should be excised at the primary operation The practice of excising certain types of duodenal ulcers and of combining the excision with the excellent pyloroplasty of Finney is becoming more and more prevalent

The preponderance of males over females with duodenal ulcer is perhaps partly due to anatomic reasons In the female, the first portion of the duodenum is more nearly transverse than in the male, so that the alkaline juices of the bile and the pancreatic secretion more or less constantly bathe the upper duodenum In the average male, the first portion of the duodenum, as a rule, passes upward, and then the second portion to the common duct descends, so that the first inch and a half of the duodenum is not so readily alkalized Perhaps one of the great merits of the Finney pyloroplasty is the change in mechanical conditions, that is, the duodenum is drawn down and sutured to the greater curvature of the stomach at the pyloric end, thus permitting not only ready emptying of the stomach, but also alkalization of the former ulcer area Recurrence of an ulcer after a Finney operation is rare However, the ease and safety of gastro-enterostomy, and the fact that it deals with sound tissues, give it great advantages over the pyloroplasty which must be done in edematous adherent scar tissues at the site of the ulcer

When gastrojejunal or jejunal ulcer occurs following gastro-enterostomy, the Finney type of operation presents great advantages Merely to excise the gastrojejunal or jejunal ulcer is to invite recurrence We find it wise to separate the gastro-enterostomy completely, close the jejunal and gastric openings, and make a Finney pyloroplasty As new ulcers may occur in the vicinity of the gastro-enterostomy in about 1 or 2 per cent of cases, the Finney operation is a valuable reserve method Closure of the pylorus, pyloric occlusion, or operations of that character, which have been shown to be wholly unnecessary, are unwise if for no other reason than because in the 1 or 2 per cent of cases in which separation of the gastro-enterostomy and a pyloroplasty becomes necessary, the pyloric procedure is more or less hampered by a previous pyloric closure or occlusion Unnecessary pyloric tinkering originated in the attempt to make gastro-enterostomy relieve disability not due to ulcer, for example, to force a tardy prolapsed stomach to empty more quickly through an unnecessary gastro-enterostomy, in the hope of relieving neurasthenia and gastric neurosis There are two causes of failure of surgery to relieve patients suffering from peptic ulcer (1) functional disturbances due to subsequent faulty dietary conditions, which the internist can relieve, and (2) mechanical disturbances due to faulty surgical methods which can be relieved by secondary surgical procedures

It was not until the surgeon penetrated the abdomen and actually saw the pathologic condition in the form of peptic ulcer that the present understanding of it was reached Previous to this development of surgery, 96 per cent of peptic ulcers were believed to be in the stomach As a matter of fact, only about 25 per cent are so situated Ulcer was believed to be a disease much more common in females than in males; in reality, the incidence is but little over 25 per cent in women It was believed that patients with ulcer suffered pain immediately after eating, we now know that temporary relief follows eating It was believed that hemorrhage was often a sign of peptic ulcer, we now know that it occurs in less than 25 per cent of cases The greater number of sudden hemorrhages from the stomach which are not preceded and followed by the ordinary symptoms of ulcer are not caused by ulcer but by superficial erosions of the gastric mucous membrane due to toxic hepatitis, the result of focal infection often originating in the appendix, gallbladder, teeth, tonsils, and so forth

Roentgenograms, correctly interpreted have been extraordinarily valuable in the diagnosis of peptic ulcer A roentgen-ray specialist attached to a medical clinic has little opportunity to perfect himself in the interpretation of shadows of gastric and duodenal ulcer Skill is acquired only by directly comparing the plate with the actual condition as disclosed at operation Every roentgenogram of the abdomen is capable of enlightening or of misleading interpretation Plates honestly but incorrectly interpreted, purporting to show certain conditions, are constantly being submitted The value of the roentgen ray in the diagnosis of gastric and duodenal lesions is measured, not by artistic success, but by the skill and experience of the interpreter In the year ending June 30, 1921, Carman and his associates diagnosed by the roentgen ray 523 cases of duodenal ulcer, in which operation was performed, the diagnosis was confirmed in 500 (95 6 per cent) cases During the same period, roentgen-ray diagnosis of gastric ulcer in 125 cases was confirmed at operation in 122 (97 6 per cent), eight of the ulcers, however, proved to be malignant In the same period, eight cases were diagnosed gastrojejunal ulcer, of which six

(75 per cent) were confirmed at operation Besides these, 7,868 cases were diagnosed as negative for duodenal, gastric, or gastrojejunal ulcer Exploration was performed in 631, and the absence of ulcer was verified in 587 (93 1 per cent)

Double ulcer, gastric and duodenal, has been found in about 6 per cent of the cases seen at the Mayo Clinic Several patients with duodenal ulcer were relieved temporarily by gastro enterostomy, and on return of symptoms were found to have gastric ulcer I have observed three such cases Perhaps the gastric ulcer did not follow the gastro-enterostomy but was present and overlooked at the time of operation A surgeon operates on a patient and finds an obvious duodenal ulcer with obstruction, the type that gastro-enterostomy is almost certain to cure, and promptly performs a gastro-enterostomy If the condition of the patient is none too good, the examination of the stomach may be cursory, and the gastric ulcer may be overlooked Such instances at least bring up the fact that the results of gastro-enterostomy alone in cases of gastric ulcer are satisfactory in only about 60 per cent of cases Excision of the ulcer, preferably by cautery, is essential to the best results

The greater number of duodenal ulcers are entirely different pathologically from gastric ulcers Chronic gastric ulcers always have craters, the majority of duodenal ulcers do not have craters, and, therefore, often are not recognized at necropsy Gastric ulcers are the callous type, and penetrate all coats of the stomach to the peritoneum In the duodenum ulcers are usually erosions, little fissures or cracks extend through to the muscular coat and peritoneum, giving the appearance of erosion as by a file, the significance of which may be missed by an observer who bases his idea of duodenal ulcer on his knowledge of the appearance of gastric ulcer Only the minority of duodenal ulcers have true craters, and such as occur are usually on the posterior wall of the duodenum

MALIGNANT DEGENERATION OF PEPTIC ULCERS

In five cases of carcinoma of the upper duodenum which came under my observation, four of the tumors were so closely connected with the pancreas or common duct that I could not determine that they were primary in the duodenum The practice of excising duodenal ulcer to obviate a liability to cancer has not a sound foundation I have, however, seen a few cases of gastric cancer in which a duodenal ulcer extended to the pylorus Whether there was causal relation between the gastric margin of such an ulcer and cancer is open to discussion

My experience coincides with that of surgeons the world over, and leads to the belief that cancer of the stomach rather often originates in ulcer of the stomach or perhaps from the same causes as those that produced the ulcer Unless the ulcer is excised, it cannot be determined whether or not its margin is cancerous A specimen of tissue removed from the base of the ulcer may not show the carcinoma if it exists only in the margin

Balfour [1] has demonstrated the ease and safety of the cautery in operations for ulcers of the stomach, and as a preventive against overlooked carcinoma on the margin of an ulcer it has been of the greatest value The heat not only destroys the ulcer but also sterilizes the nuclei of the malignant cells at a distance, by selective effect, so that, following this procedure, recurrence of carcinoma has been extraordinarily reduced, as compared with that following knife excisions

Putting aside evidence derived from operating room experience, which might be influenced by the character of the lesions to be resected, I wish to call attention to some valuable collateral evidence Von Eiselsberg, studying the material at the Vienna Hospital, in reference to the ultimate results of the surgical treatment of gastric and duodenal ulcers, showed that of forty-one deaths at dates remote from operation thirteen were known to be from cancer of the stomach But, since only twenty-three postmortems were held, it is readily seen that the thirteen known cases of carcinoma of the stomach were not representative of the total group of forty-one but of the group of twenty-three It should be remembered also that von Eiselsberg's cases were both of gastric and of duodenal ulcers, that ulcers exist in a ratio of three duodenal to one gastric, and that duodenal ulcers do not have a tendency to become cancerous The statistics of Joslin [2] of the Massachusetts General Hospital, showing that 24 per cent of the late deaths following gastric and duodenal ulcers were from cancer of the stomach, are pertinent Again, it may be noted that duodenal and gastric ulcers were grouped together, and probably only one-fourth could be considered gastric ulcers and, therefore, as having a cancer liability

Standard life insurance companies were anxious to know whether or not patients who had been operated on for gastric and duodenal ulcers were insurable Mr Hunter, actuary of the New York Life Insurance Company, with his staff, investigated 2,323 cases at the Mayo Clinic in which operations had been performed for gastric and duodenal ulcers The results proved that the death rate in cases of duodenal ulcer, in the five years following operation, was no higher than the average for the same age and condition in the insurable risks as shown by the life insurance mortuary tables, while the rate in the gastric ulcer group was three times that of the normal risk In 1914, Wilson [3] summarized the results of a study of resected tissue containing the primary carcinomatous lesion in 399 cases of gastric cancer seen at the Mayo Clinic, nineteen (4 8 per cent) showed ulcers with doubtful cancer in the border Photomicrographs from five of the nineteen cases had been shown before the Association of American Physicians in 1909, when they were considered by the members who examined the slides to be benign ulcer Three of the five patients died of cancer in the next five years

SUMMARY

1 Duodenal ulcer is treated satisfactorily by surgery in approximately 95 per cent of cases, although in 1 or 2 per cent of these a second operation may be required The ulcer is not associated with cancer liability

2 The average operative mortality in cases of duodenal ulcer, including the acute and chronic cases, is under 2 per cent from all causes, and, as the part of the duodenum usually involved is merely the vestibule of the small intestine, permanent interference with function is slight

2 Joslin, E P End Results in Cases of Gastric and Duodenal Ulcer J A M A 63 1836 1839 (Nov 21) 1914

3 Wilson L B and McDowell I E A Further Report of the Pathologic Evidence of the Relationship of Gastric Ulcer and Gastric Carcinoma Am J M Sc 148 796 816 1914

3 In cases of gastric ulcer, satisfactory results are obtained by one operation in more than 85 per cent In the remaining cases, a secondary operation, preferably resection, which eliminates, to a great extent, future ulcer possibilities, brings the surgically satisfactory group of gastric ulcers well above 90 per cent, but there is a definite cancer liability in the years to follow

4 The average mortality in the operative treatment of cases of gastric ulcer, including the acute and chronic cases, is about 3 5 per cent The stomach has important functions to perform and a certain amount of permanent crippling may result

5 In about 50 per cent of the patients who fail to obtain satisfactory relief, the difficulty is functional and can be relieved by medical management The other 50 per cent must be classified as surgical failures due to faulty mechanics, and will require secondary corrective surgical procedures for relief

6 The patients' general condition must be considered and rational habits of living established The elimination of all sources of focal infection is also an essential measure

RELATIVE VALUE OF SURGICAL AND MEDICAL TREATMENT OF GASTRIC AND DUODENAL ULCER*

ARTHUR DEAN BEVAN, M D
CHICAGO

During the last ten years or more I have had the opportunity of making, with my medical colleagues at the Presbyterian Hospital, a combined study from both the medical and surgical points of view of the subject of peptic ulcer I believe that we have approached this matter with open minds and have attempted, in this clinical research, first, to establish the relationship between the clinical picture and the pathologic anatomy, and, secondly, to determine the value of both the medical and the surgical treatment and the indications for each During this period of ten years, of course, similar researches have been made in a large number of clinics, both in this country and abroad, notably by workers in the Mayo Clinic at Rochester, by the Leeds group in England, headed by Moynihan, by von Eiselsberg and his assistants, Haberer and Clairmont, and by Schmieden, who was formerly with Bier and who now has a chair of surgery at the new university at Frankfort, and, of course, my many others

ETIOLOGY OF PEPTIC ULCER

I shall attempt to summarize briefly the results of my experience with this problem In the first place, I think it might be well to discuss the present status of our knowledge of the etiology of peptic ulcer Peptic ulcer is a lesion in the causation of which a number of factors play an important part, but, of course, that is true of almost all lesions Take, for instance, such a simple lesion as a furuncle on the back of a man's neck I have for years taught my students that here we had at least three causative factors, and I have expressed the matter by the algebraic equation X + Y + Z = furuncle In this equation X is the essential germ cause, usually *Staphylococcus aureus,* Y is the small abrasion produced usually by a rough collar, which furnishes the atrium of infection, Z is the general lowered resistance of the individual that permits of the growth of the organisms in his tissues These three factors combined produce the resulting boil

I think peptic ulcer is a more complicated condition than the simple boil and that we have at least three, and probably more, factors in its causation If we expressed these in terms of the same algebraic formula, we would have X + Y + Z = peptic ulcer I am rather inclined to consider the X in this equation as the gastric juice with its power of digesting devitalized tissue I place this first because it is the characteristic factor of peptic ulcer Peptic ulcer does not occur in the absence of gastric juice Y is an area of lowered local resistance, resulting usually from some injury or lesion of the blood vessels of the mucous membrane, interfering with the blood supply of a small area of tissue and so lowering its vitality that the gastric juice can destroy and digest it Z is again the lowered general resisting power of the individual, which, I believe, in this case presents probably a rather complex picture, as this lowered resisting power may be due to a number of quite different causes

First, anemia is undoubtedly one of the conditions lowering the resisting power of the patient General poor nutrition is an important factor This was well demonstrated during the last war when the hunger blockade of the central European countries was followed by an enormous increase in peptic ulcer, due to the lack of proper food and to the ingestion often of food that was difficult to digest Another factor which lowers the resistance of the individual and plays an important part in the production of peptic ulcer is increased nervousness of the patient Nervous strain (worry) is recognized by many investigators as being one of the important factors in the development of peptic ulcer This may produce its effects in several ways, increasing possibly the high acid content of the gastric juice and possibly producing pyloric spasms or possibly lowered resistance against the action of gastric juice by impairment of proper nerve function, although the last suggestions are, of course, purely theoretical I believe we can safely say that all these factors—the X + Y + Z, which I have described—play important parts in the production of peptic ulcer

There has been of late years a good deal of investigation directed toward demonstrating that focal infections, such as infected teeth and tonsils, an infected appendix or an infected gallbladder, may cause peptic ulcer by producing hematogenous septic infarcts of areas of the mucous membrane of the stomach Rosenow has particularly called our attention to this point There can be no doubt that infections occur in which we have the picture of an acute ulcer of the stomach or duodenum which results from a hematogenous infection or septic embolism of a vessel of the mucous membrane of the stomach and duodenum, from a focus of infection, such as the tonsils or teeth, or from an extensive area of skin infection following a burn My own impression is that these acute cases usually heal promptly or if they are very serious they may result fatally, but I believe that they are not the ordinary common cause of the cases of peptic ulcer of the stomach and duodenum which we see clinically, and that the infection from pus organisms plays a minor role in the causation and the persistence of peptic ulcer

* *Read before the joint meeting of the Section on Surgery General and Abdominal and the Section on Gastro Enterology and Proctology at the Seventy Third Annual Session of the American Medical Association St Louis May 1922*

SYMPTOMS

My conception of the symptoms of peptic ulcer, especially the essential and common symptom of stomach distress, I shall present very briefly The sensations experienced by the patient with peptic ulcer may be described as sensations of discomfort or distress, or of actual pain We surgeons who operate today, very frequently under local anesthesia, on abdominal viscera recognize the fact that we can handle the stomach and duodenum with little or no distress to the patient We can sew the stomach and intestines together as in a gastro-enterostomy without any sensation We can burn off the end of the stomach or duodenum with a cautery without causing any sensation, and we sometimes wonder why an ulcer in the duodenum or in the stomach produces pain and how it produces pain We know that if in performing an operation under local anesthesia we pull on the viscera we can produce very great pain We know too that in the abdominal cavity the most common cause of pain is distention of some viscus, as is clearly shown in the great pain resulting from obstruction of the cystic duct in gallstone colic, or the great pain resulting from obstruction of the ureter in kidney stone colic, or the great pain resulting from the obstruction of the bowel in ileus In these cases we can quite clearly see and can demonstrate experimentally and clinically that it is the intravisceral tension which produces the pain We know too that tissues that are the site of an inflammatory process are much more painful than the normal tissues in the abdominal cavity

Pain, as I have studied it in peptic ulcer, occurs under three conditions first, when there is an intravisceral tension due to the distention of the stomach or the bowel with gas and food, and associated often with obstruction or a spasm preventing the normal emptying of these viscera, secondly, when there is irritation caused by the gastric juice on the raw surface of the ulcer, the so-called chemical pain, and thirdly, when there is lighting up of an acute inflammatory process in and about the ulcer itself This sort of pain is liable to produce a picture in a patient with duodenal ulcer resembling very closely that of a gallstone attack I have been able to unravel a number of cases in which because the character of the pain so closely simulated gallstone colic we had made that clinical diagnosis before operation and in which at operation I have found no lesion of the gallbladder but an inflamed and often a penetrating ulcer, usually either in the duodenum or in the stomach, and close to the lesser curvature

Personally, I can understand quite well stomach and duodenal pain which results from intravisceral tension and pain which results from an acute inflammatory process developing in and about the ulcer In the light of the fact that we can crush a part of the stomach or the duodenum or cut it off or destroy it with a cautery without producing any sensations to the patient, it is difficult for us to understand how gastric juice poured over the raw surface of an ulcer can produce pain, unless we accept the proposition that in this pathologic condition of ulcer the tissues are more sensitive than under normal conditions This I consider is the fair and logical explanation of the facts I am quite willing to accept the generally accepted belief that the ordinary pain of peptic ulcer is due to pouring over the raw surface acid gastric juice with a high free hydrochloric acid content and I believe we are compelled to accept this point of view by the results [illegible] constantly observe of the neutralizing [illegible] chloric acid with alkalis, with the resu[illegible] and disappearance of the pain Howeve[illegible] that intravisceral tension plays a definite [illegible] part in the distress and pain of peptic ulc[illegible] in almost all painful conditions of the ab[illegible] viscera I believe that this phase of peptic ulcer deserves special study and that when this problem is solved we will have learned that here, as in almost all painful abdominal lesions, intravisceral tension plays an essential part

HEALING OF PEPTIC ULCER

In regard to the healing of these ulcers, I want to draw a parallel, as I have done in my own study, between the ordinary varicose ulcer of the leg and peptic ulcer We can study the healing process of a varicose ulcer and watch the process directly under our eye from day to day First, let me again suggest the algebraic equation $X + Y + Z =$ varicose ulcer In this algebraic equation the X, the essential and characteristic factor in the etiology, is the obstruction of the return circulation, Y is usually some slight traumatism of the skin This slight injury becomes the starting point of an ulcer, sometimes of considerable size Instead of healing, the tissues about the injury break down and the ulcer grows in size Z is the general resisting power of the individual again and this is modified by poor nutrition, poor hygienic surroundings, hard work and general constitutional disease If one makes a culture of the secretions of the varicose ulcer he will have no difficulty in demonstrating pus organisms of various kinds and often saprophytic organisms I believe, however, that these organisms do not play an important part, either in the production of the ulcer or in preventing wound healing Of course, at times, a varicose ulcer becomes acutely infected and inflamed I would draw, therefore, a close parallel between the varicose ulcer and the peptic ulcer as far as pus organisms are concerned, that is, they are present in both, they are, however, as a rule simply an incident and they may occasionally be the cause of lighting up of an acute infection, but they are not the essential cause of the ulcer

Now let us examine the natural history and the wound healing of a varicose ulcer I believe I can speak on this subject with some authority since I have watched carefully a large number of these cases Keeping in mind the X and Y and Z which equal varicose ulcer, if we place the patient at absolute rest in bed in a recumbent position and elevate the affected leg we do away for the time being with the X, the most essential factor in the production and maintenance of varicose ulcer, that is, the interference with the return circulation If we do only this, without attempting to do anything else, as a rule in a very limited period (from ten days to two weeks or more) the ordinary varicose ulcer will heal In the healing process the bacteria which are on the surface gradually disappear and granulations become healthier, and with the complete epidermization of the ulcer the bacteria disappear entirely If the general condition of the patient is bad, if the patient is anemic, run-down from any cause or undernourished, improved hygiene, better food, fresh air, cleanliness and attention to proper elimination are important in improving the general condition of the patient Under this improved general condition, wound healing is more rapid

? there is a combined condition, such as varicose ulcer plus syphilis, antispecific treatment is of very definite value In other words, the history of a leg ulcer is that when we remove the essential cause and contributing causes and place the patient and the part involved in the best possible condition for healing, especially when we remove the essential cause—the interference with the return circulation—wound healing, as a rule, occurs promptly

There are, however, some exceptions to this rule The old time surgeons recognized perfectly well the existence of some of these old leg ulcers of a certain type which they called "callous ulcers" If you examine one of these you will find a rim of very dense scar tissue around the ulcer, and in the crater-like depression of the ulcer itself In these callous ulcers, wound healing is very slow and sometimes almost impossible to obtain with the ordinary elevation of the limb, rest and improved general condition of the patient, which is in varicose ulcer of the ordinary type so efficient Old time surgeons understood this problem very well and in order to heal one of these ulcers they would dissect out the hard indurated callous margin of the ulcer and the base of the ulcer itself, then place the patient in a recumbent position and treat the ulcer as the varicose ulcer of the ordinary type and obtain in this way wound healing

There is a third type which one might mention in continuing this parallel between the varicose and peptic ulcer, and that is the old chronic ulcer in which such great changes have occurred at the site of the ulcer that the tissues have apparently lost their power of repair, and not infrequently in these cases we must resort to dissecting out the ulcer and employing either skin grafting or covering the area with a flap by some plastic operation

I should like now to ask you to keep in mind this picture of varicose ulcer as I have drawn it and apply it to the study of peptic ulcer I am thoroughly satisfied that very much the same thing happens in the ulcer in the interior of the stomach and duodenum that happens in the ulcer of the leg If we can place a peptic ulcer under conditions in which we eliminate, as we can do in a varicose ulcer, the essential causes which produce and maintain the ulcer, we can in the vast majority of cases succeed in producing wound healing on the interior of the stomach and duodenum just as we can on the external integument In order to do this it is clear that we must place the patient at rest in bed and we must place the stomach and duodenum at rest as much as possible There is no doubt in my mind but that rest in bed is very desirable, certainly for several weeks Local rest of the stomach and duodenum are obtained by removing food traumas and by the blandest possible diet This, of course, is the practical method which we employ in clinical work

We can demonstrate absolutely the value of rest in the healing of these peptic ulcers by the results which can be obtained from the operation known as jejunostomy If, for instance, under local anesthesia, we pick up the first part of the jejunum and introduce a small rubber tube into the intestine, performing the operation with good technic so as to prevent any leakage and resulting peritonitis, and if we keep this tube in the jejunum for a number of weeks, or even months, and put nothing of any kind in the stomach but feed the patient entirely through this jejunostomy tube, we, in this way, of course, place the stomach and duodenum at absolute rest and we can cure almost any of the peptic ulcers in the stomach or duodenum in this manner That has been demonstrated now in a number of cases I think we should keep this in mind as a very definite illustration of the importance of rest in the management and the healing of peptic ulcers

In the next place, and most essential, is the neutralizing of the acid of the gastric juice so as to prevent the irritating digestive effects of the gastric juice on the raw ulcer surface We must place the patient, handicapped as he is by being in bed, under the best possible hygienic conditions as far as food, fresh air, nursing and massage are concerned to improve his general condition In the large majority of peptic ulcers, rest of the patient in bed, rest of the stomach and duodenum, neutralization of the gastric juice and improvement of the general condition of the patient will result, in the course of some weeks, or possibly several months, in a complete healing of the ulcer There are, however, *very definite exceptions to this rule I believe there is* no doubt that old callous ulcers of the stomach and duodenum are often very refractory, just as are old callous ulcers of the leg, to this rest treatment, and when the ulcer is situated so as to impair seriously the functions of the stomach and duodenum, as at, or near, the pylorus, producing obstruction and deformity, complete wound healing cannot, as a rule, be obtained by medical management alone

I desire by the rather rough outline which I have drawn to present to you the conception that both the ulcer of the leg and the ulcer of the stomach and duodenum are the result of a number of causative factors, that when we recognize these factors we are then in a position to apply this knowledge in a practical way to the cure of the disease, and that the cure depends on the recognition of the principle that if we eliminate altogether or in large part the causative factors we can, as a rule, place the patient and the local lesion in a condition in which wound healing can go on to completion and we can cure the disease Although we can cure the great majority of peptic ulcers by medical management on the principles which I have outlined, there remains a considerable number of cases, just as in ulcers of the leg, in which we must resort to something more than medical management, namely, to surgical treatment of one kind or another

We can cure a varicose ulcer of the leg by proper treatment We can cure a peptic ulcer by proper treatment We want to remember, however, that the ulcer in either case may recur, that it may recur at the original site or a new ulcer may develop, and that this is liable to happen unless we take pains to eliminate, to some degree at least, the causes which produced the ulcer in the first instance

In the case of the varicose ulcer the important factor of interference with return circulation can be remedied often by wearing a proper bandage or by a surgical operation, removing a segment of the veins and breaking the long column of blood In the case of the peptic ulcer, if we are to prevent recurrence, which is unfortunately common, we must, by proper attention to diet and the general condition of the patient, eliminate the acidity and food traumas, the nervous tension and the bad general conditions which were responsible for the ulcer in the first instance The person who has been cured of a peptic ulcer must know that the price of a permanent cure is eternal vigilance, and this

is true whether the cure has resulted from medical management or surgical operation

SURGICAL TREATMENT

Now let us turn to the surgical treatment of peptic ulcer Surgical treatment includes operations for perforation, for pyloric obstruction for hour-glass stomach and operations performed for the actual removal—the resection—of the ulcer It includes also gastro-enterostomy and jejunostomy There can be no question, of course, about the necessity and great value of the surgical treatment for perforation and for cicatricial and unyielding pyloric obstruction and for hour-glass stomach in which the deformity produces symptoms All internists and surgeons agree that these conditions demand surgical treatment

What can surgery do to cure chronic peptic ulcer of the duodenum and stomach

1 The ulcer may be excised by one of several methods and the patient cured by an operation which carries a certain amount of risk, which varies enormously with the skill and experience of the operating surgeon

2 Ninety per cent of ulcers of the duodenum and 50 per cent, or more, of ulcers of the stomach may be cured by gastro-enterostomy, which again carries a certain amount of risk, probably less than 2 per cent in skilled hands, with an associated risk of developing a jejunal ulcer in 3 per cent, or more, of the cases

How does gastro-enterostomy cure an ulcer in the stomach and duodenum? This has been answered in several ways Patterson believes that the important factor in the cure is the neutralization of the acid gastric juice by the alkaline bile and pancreatic juice which results from their pouring into the stomach through the new opening Admitting that there is probably some truth in this theory, I believe that the value of a gastro-enterostomy is in the safety valve action of the new opening, the relief of tension Let us apply this conception to a gastro-enterostomy performed for a duodunal ulcer, in which the prospects of cure are, I believe, 90 per cent I visualize the result in this way As soon as the gastro-enterostomy is performed, spasm of the pylorus prevents the gastric contents from passing into the duodenum, and, as a result, the gastric juice and food take the course of least resistance and pass out through the new opening The duodenal ulcer is thus put at rest, is protected from the irritating actions of the gastric contents and wound healing proceeds rapidly and the ulcer heals As soon as the ulcer heals, or possibly even when it begins to heal and becomes covered with healthy granulations, the pyloric spasm ceases, in whole or in part, and the gastric contents begin to take the normal course through the pylorus In my mind, one of the reasons for the marked relief which follows gastro-enterostomy is probably the relief from intragastric tension which the gastro-enterostomy affords In the case of the cure of a gastric ulcer produced by a gastro-enterostomy, I believe relief from gastric tension, the freer emptying of the stomach and the neutralization of the gastric juice by the bile and pancreatic juice furnish the logical explanation

I have already referred to the cure of peptic ulcer by jejunostomy Here the explanation is very definite The ulcer, whether in the stomach or duodenum, is at once placed at rest by feeding the patient through the jejunal tube and healing usually progresses rapidly The operation is, however, in spite of its efficiency, not a very practical method of treatment and should be reserved as a preliminary procedure in seriously handicapped patients In one case, by a jejunostomy I was able to save the life of a man who had at the time of the operation but 17 per cent hemoglobin

What can be said of the operations for excising peptic ulcers? This can be accomplished either by an oval or wedge-shaped excision, when the conditions permit, or by transverse resection of the stomach or by what is now being tried rather extensively, a resection of the stomach and duodenum by the Billroth II and the Billroth I operations The excision of the ulcer seems the ideal treatment The risk, however, is considerable It is the operation of choice when it can be performed without great risk and without resulting deformity A new chapter is being written at this time in stomach surgery by the men who are performing the extensive resections of the duodenum and stomach, which are termed the first and second Billroth methods These operations have proved, in the hands of a few expert surgeons surprisingly successful Moynihan, Haberer, Clairmont, Eiselsberg and Schmieden have reported series of fifty or more cases, with from 1 to 2 per cent mortality I have been much impressed with the value of the Billroth II excision for ulcer and am trying it out in a series of cases, especially in cases of callous ulcers in which the possibility of carcinoma must be considered

The Billroth excision accomplishes definitely three things (1) It removes the ulcer (2) It removes the pylorus and the element of pylorospasm (3) By removing a considerable amount of the secreting area of the stomach, it diminishes the free hydrochloric acid content of the gastric juice, and finally it removes, with the ulcer area, a possibly existing or a potential carcinoma

MANAGEMENT OF PEPTIC ULCER

Now that we have reviewed the essential principles of this subject, let us ask ourselves how we shall apply this knowledge to actual practice, let us say in a hundred ulcer cases? I believe that we can make this matter simpler and clearer if we answer the question With our knowledge of this subject, how would you and I like to have an ulcer of the stomach or duodenum treated? After all, this is the real test If I had a peptic ulcer, uncomplicated by any of the conditions which, we all agree, demand surgical treatment, perforation, pyloric obstruction from scar, etc, I should want it treated by a scheme of sound medical management and would place myself in the hands of my colleagues, Sippy or one of his disciples, because I believe that he has worked out the best method so far devised I believe that my chances of cure would be from 80 to 90 per cent, and that I could keep well if I took reasonable care of myself I would recognize the fact that there was a certain definite risk of recurrence How large this is is difficult to state in figures

If I had had repeated hemorrhages and the evidence showed the ulcer was probably in the duodenum, I should want to be operated on by one of my good surgical colleagues who had devoted special attention to this subject and I should want a gastro-enterostomy performed If in the course of the disease persistent pyloric obstruction developed I should want a gastro-enterostomy performed If in spite of good medical management, I was not completely cured and symp-

toms recurred on slight provocation, I should want a gastro-enterostomy performed If in spite of good ulcer management, the symptoms persisted I should want to be handled as a carcinoma suspect and be given the benefit of an exploratory operation If at the operation a callous ulcer was found on the stomach side of the pylorus, I should want the benefit of a second Billroth operation If I had an operation for ulcer, either a gastro-enterostomy or a resection, I should want to be given medical ulcer management as a part of the after-care for the purpose of reducing to a minimum the chances of a jejunal ulcer

If I attempt to put the question of the medical and surgical treatment of ulcer in figures, I should do so in about this way Almost all ulcers in their early history should be treated medically When they persist under good medical management, when they recur in spite of good medical management and the care which the patient can obtain in his or her peculiar station of life, when serious and repeated hemorrhages occur, when pyloric obstruction does not yield to good medical management, when there is a reasonable suspicion of malignancy, in all of these cases medical management should not be too long persisted in but should give way to exploration and surgical therapy as the safer plan and the plan which affords the better prospect of cure Numerically, I believe that these cases demanding surgical treatment for their best interests would constitute about 10 per cent of the ulcers of the chronic type

To visualize this a little more clearly, let us take 100 cases of peptic ulcer Practically all of these should be given at first the benefit of sound medical management Possibly ninety of these patients may be cured and kept well by medical management Probably 10 per cent of these cases, after repeated trials of medical management, will prove refractory and should then be given the benefit of exploratory operation and surgical therapy I have no sympathy for the position taken by some surgeons that ulcer of the stomach and duodenum are conditions like gallstone disease that are to be relieved by surgical operations Nor have I any sympathy with the position taken by some gastro-enterologists, that all ulcer cases must be treated medically and that surgical therapy should be put off as long as possible and be regarded simply as a last resort To my mind, the great value of medical management has been clearly shown, especially by Dr Sippy and his disciples They have shown that peptic ulcer can be cured by medical management and that the great majority of patients can be so cured

On the other hand, no more brilliant chapter has been written in the history of surgery than the chapter on gastric and duodenal ulcers We owe to our surgical colleagues most of the knowledge that we have of gastric and duodenal ulcers, the knowledge which we have obtained by the autopsies in vivo which we have made in the last twenty years Twenty years ago, we hardly knew that there was such a thing as a duodenal ulcer The surgeons furnished us with the knowledge of its existence and its frequency The surgeons made mistakes in the development of this subject They performed too many gastro-enterostomies They placed too little value on medical management

But in spite of mistakes, great progress has been made and today we can say with much confidence that in the cases of ulcer which prove refractory to medical management, modern surgery offers much to these patients The ideal situation is the joint treatment of these cases by internist and surgeon, who realize the field of usefulness and the limitation of both the medical and surgical management and who give to their patients the benefit of their combined judgment and the treatment demanded in each individual case

122 South Michigan Avenue

RELATIVE VALUE OF MEDICAL AND SURGICAL TREATMENT OF GASTRIC AND DUODENAL ULCER*

BERTRAM W SIPPY, M D
CHICAGO

The relative value of medical and surgical treatment of peptic ulcer and the indications for each are dependent on a number of factors Among these, three stand foremost The first factor has to do with the conditions and complications that attend the ulcer The second involves a careful consideration of the character of the surgical treatment to which the patient is to be subjected Herein, the skill of the surgeon who is to perform the operation is of the utmost importance, since it influences enormously the immediate mortality and, to a lesser degree, the late bad effects of the operative treatment of the disease The third pertains to the straightforwardness with which the type of medical treatment employed combats or removes the conditions that retard or prevent healing and thus contributes to the eradication of the ulcer and its complications

Careful analysis of these three factors should more frequently serve as a basis for choice of method to be employed Proper analysis of the first factor necessitates an accurate study of the case for the purpose of revealing the conditions and complications that attend the ulcer If one knows what to look for and how to go about it, prolonged study of the case is seldom required for an exceedingly trustworthy investigation relative to the presence of ulcer and such important conditions and complications as may attend it Then the question so often contemplated in the improper form Should peptic ulcer be treated surgically or medically? becomes one easier of solution in this form Should this particular ulcer, with the recognizable conditions and complications that attend it, be treated surgically or medically or by combining both methods?

Obviously, the best answer to such a question cannot be given without a thorough and unbiased understanding of what may be done by each of these procedures to relieve the symptoms of distress and eradicate the disease Then the discomforts, probability of cure and, last, but not least, the mortality that is likely to attend the adoption of such surgical or medical measures as are to be applied to that particular patient must be carefully weighed in the balance before proper choice of procedure can be made

SURGICAL TREATMENT OF PEPTIC ULCER

The surgical treatment of ulcer and its complications incorporates two methods of attack The method that has been, and still is, the most widely used leaves the

* Read before the joint meeting of the Section on Surgery General and Abdominal and the Section on Gastro Enterology and Proctology at the Seventy Third Annual Session of the American Medical Association St Louis May 1922

ulcerated area virtually unchanged at the time of the operation, but employs measures that tend to remove complications and distress symptoms and to bring about conditions that contribute to the healing of the ulcer Gastro-enterostomy for pyloric obstructive ulcer is the most common and, when successful, the most effective procedure representing this method of attack

The other method makes a direct attack on the ulcer and attempts to reduce it in size or to remove it The two methods of attack are combined, under certain conditions It is to be understood that in proportion to the number of cases of peptic ulcer treated surgically, relatively few ulcers have been removed directly by operative procedure Inaccessibility, due to location, adhesions or other unfavorable conditions, not infrequently render removal of the ulcer impossible In those cases in which the ulcer-bearing area has been accessible, the mortality attending excision and resection has heretofore very generally caused the surgeon to hesitate to employ either of these two surgical procedures as a substitute for, or in addition to, gastro-enterostomy

Within recent years, there has been a growing tendency among the most skilful surgeons to adopt the direct method of attack, employing such measures as excision of the ulcer with knife or cautery, reducing it in size by cautery or suture, resecting that portion of the duodenum or stomach containing the ulcer and incorporating a removal of the ulcer in pyloroplastic operations In the surgical treatment of gastric ulcer, a tendency to remove more and more of the stomach is apparent Partial gastrectomy is being performed and advocated by some of the experts as the ideal toward which surgical skill should be directed Sir Berkeley Moynihan has published articles portraying the failures and bad results following excision of ulcer alone or combined with gastro-enterostomy and reports a death rate of 4 7 per cent following partial gastrectomy in his service A symposium on the end-results of the surgical treatment of gastric and duodenal ulcer, in which several exceptionally well trained experts in gastric surgery participated, was held in Washington this month The mortality resulting from surgical treatment contained in these reports ranged from 6 to 8 per cent It is probable that an exceedingly few, exceptionally eminent supersurgeons are able to quote figures indicating a lower mortality A death rate of one for every thirteen to twenty patients operated on in the services of such men as those reporting at the Washington conference is a matter for thoughtful consideration, when contemplating the relative value of surgical and medical treatment of peptic ulcer

When one considers that the vast majority of all patients with peptic ulcer treated surgically are operated on by men of much inferior training—men who when challenged to operate by having a case referred to them, attempt to imitate the technic of the expert surgeon—one can readily understand that the mortality that attends the surgical treatment of ulcer must range from 1 to 100 per cent, depending on the skill of the operator In many instances, the medical practitioner referring the case has watched the skilful surgeons at the noted clinics, listened to their addresses, read their articles and has become convinced that the operative treatment of peptic ulcer is relatively easy, and that the results justify the risk involved Thereupon, being confronted by a patient afflicted with peptic ulcer, he sends the patient to a surgeon of local reputation who has operated and strives to imitate men who, through years of unusual training and experience, have acquired a low mortality

It is during this striving and never arriving period of the surgeon's development that the mortality of the surgical treatment of peptic ulcer is likely to be high Unless human nature changes, the development of the so-called system of group practice is likely to warp the judgment of many medical practitioners in favor of the surgeons of their particular groups

With the exception of certain types of resection and pyloroplastic operations, nearly all of the operative procedures are performed in conjunction with gastro-enterostomy It is recognized that jejunal ulcer following gastro-enterostomy becomes manifest clinically in 2 or 3 per cent of the patients who survive the operation It is improbable that this percentage even approximates the total number that develop and either heal spontaneously or persist without symptoms Similar to the nonobstructive type of ulcer, a jejunal ulcer is likely to be latent unless it penetrates to, or through the peritoneal coat or erodes a large blood vessel, thus causing hemorrhage sufficient to attract attention Aside from the development of jejunal ulcer, the late bad effects of well conducted operative procedures for peptic ulcer are seldom of serious moment

Brilliant as are the results of surgical treatment when applied to such cases of peptic ulcer as clearly require the services of the surgeon, sufficient evidence may be found upon thoughtful consideration to cause one to hesitate to advise surgical treatment for the relief of peptic ulcer unless the conditions are such as to render operative treatment necessary or a surgeon highly skilled in the technic of gastric surgery is to perform the operation

May there not be a method fraught with less danger when applied in a world-wide way to that portion of the public afflicted with ulcer?

MEDICAL TREATMENT OF PEPTIC ULCER

What may be done by medical treatment to relieve the distress symptoms and contribute to the eradication of the ulcer and its complications? Obviously, medical treatment can contribute directly to the eradication of the ulcer only by employing such measures as promote the healing of ulcer Likewise, when the surgical treatment of the disease does not include a direct removal of the ulcer, eradication of the ulcer by the surgical measures employed must act by establishing conditions that promote the healing of the ulcer Gastro-enterostomy, the operation most frequently performed for the relief of peptic ulcer, does not remove the ulcer The ulcer cannot cease to exist without undergoing a definite healing process terminating in a mature cicatrix It must be obvious, therefore, that except in those instances in which surgical treatment includes removal of the ulcer, both surgical and medical treatment contribute directly to the eradication of ulcer only by promoting its healing Nature fills in the defect All that medical or surgical treatment can accomplish toward directly promoting the healing process is to remove such hindrances to healing as may exist For many years two essential factors have been recognized as contributing to the development and chronicity of the clinical type of peptic ulcer (1) local malnutrition or necrosis of the mucous membrane or walls of the stomach or duodenum is regarded as the initial factor, (2) the destructive action of digestive gastric juice on such local areas of malnutrition or necrosis as exist

Well nourished and otherwise undamaged tissue fully resists peptic digestion It matters not whether the tissue is protected by its normal coverings or whether raw surfaces are exposed The rapid healing of the usual experimental ulcer produced, for example, by the injection of silver nitrate is thus explained Unquestionably peptic ulcer develops and, attended by few or no symptoms, heals without treatment in an enormous number of instances The tissue adjacent to, and constituting the surfaces of such ulcers is enabled through adequate nutrition or vitality successfully to resist the eroding action of the gastric juice and such other hindrances to healing as may exist All accumulated evidence has demonstrated that when tissue, lowered in vitality, from any cause, is exposed to the digestive action of the gastric juice, the surface of that tissue becomes eroded The healing of peptic ulcer is retarded or prevented by the eroding action of the gastric juice proportionately to the diminution in the vitality of the tissue exposed in the ulcer and the constancy with which digestive gastric juice is in contact with the ulcer The digestive or eroding action of gastric juice is due to the solvent action of pepsin in the presence of free hydrochloric acid As an eroding agent, gastric juice is absolutely inert in the absence of free hydrochloric acid When the vitality of the tissue present in the surfaces of a gastric or duodenal ulcer is lowered sufficiently to render it susceptible to gastric juice digestion, the maximum efficiency of medical treatment cannot be attained without bringing about an accurate neutralization of the free hydrochloric acid as advocated in my articles, beginning with the year 1912, and carried out with increasing accuracy and improved results in our clinical work since the year 1903

With the free hydrochloric acid accurately controlled in the manner advised, the greatest known hindrance to the healing of ulcer that is amenable to medical or surgical control is removed The conditions for the healing of the ulcer are rendered as ideal as possible in the light of all accumulated knowledge The beneficial influence of gastro-enterostomy in bringing about a cure of gastric and duodenal ulcer through a reduction in the free hydrochloric acidity from 14 to 30 per cent, as is asserted, and more particularly through the accelerated emptying of the stomach, thus reducing the duration of gastric juice contact, has been the recognized explanation of the wonderful relief of symptoms and the apparent and real cures following successful gastro-enterostomy when applied to ulcer associated with pyloric obstruction It is important to realize that a reduction in the degree of free hydrochloric acidity short of its complete neutralization does not in the least diminish the peptic activity of the gastric juice

The higher the grade of obstruction, the greater the benefit of the operation In high-grade obstruction the contact of the irritant contained in the gastric juice is reduced from twenty-four hours to between nine and fifteen hours each twenty-four-hour period If the healing of obstructive ulcer is so greatly favored by such a limited reduction in the duration of peptic gastric juice contact, is it not logical to conclude that the healing of the ulcer would be much more greatly favored by destroying virtually all peptic activity by alkalis in carefully regulated doses, thus much more efficiently protecting the ulcer from gastric juice contact than can be accomplished by gastro-enterostomy or any other operative procedure that does not occlude the pylorus? Pyloric occlusion has become, with rare exceptions, an unpopular surgical procedure Our work has demonstrated that, as a result of the constant protection of the ulcer from digestive gastric juice contact, one of the most common and serious complications of peptic ulcer—namely, pyloric obstruction—is likely to yield rapidly In approximately 85 per cent of all cases of pyloric obstruction due to ulcer, ranging from the lowest to the very highest grade, the obstruction is overcome during the first three weeks of treatment to such a degree that a full meal of ordinary food is discharged through the pylorus within the normal seven-hour period In such cases the obstruction is not due to actual tissue narrowing but presumably to spasm of the pyloric muscle, acute inflammatory swelling and rarely to local peritonitis In the remaining 15 per cent of cases, the obstruction yields more slowly and is due to actual tissue narrowing which cannot be completely overcome without surgical interference in approximately one half of these cases

As far as the hindrance to healing occasioned by the digestive gastric juice is concerned, the conditions for the healing of the obstructive type of ulcer following gastro-enterostomy are rendered approximately the same as those present in the nonobstructive gastric or duodenal ulcer without treatment It must be remembered that after gastro-enterostomy the stomach does not empty itself of ordinary food and its accompanying secretion appreciably earlier than the normal time and that the stomach continues to discharge its contents through the pylorus in quantity proportionate to the size of the opening through it In all cases in which pyloric occlusion is not included in the operation, the opening through the pylorus is sufficiently large to insure the contact of digestive juice with the ulcer for the entire time that food and its accompanying secretion are present in the stomach—an aggregate of nine to fifteen hours each day

Following gastro-enterostomy for the relief of pylorus obstruction, greater efficiency may be secured and the end-results improved by including in the after-treatment of the case an accurate neutralization of the free hydrochloric acid as advised

RELATIVE VALUE OF THE TWO METHODS

It would seem fair to conclude that in the absence of certain conditions and complications, such as are recognized by all as requiring immediate or subsequent surgical relief, the skill of the surgeon who is to perform the operation and the type of medical treatment that is to be employed should be the important factors influencing the choice of procedure in a given case In general, I am in close agreement with the statements made by Dr Bevan in his paper regarding the indications for surgical treatment provided the medical treatment employed is to be of the most efficient type, as implied in his paper When, however, patients with peptic ulcer are to be placed on medical treatment based almost entirely on empiricism, developed and handed down virtually unchanged in effectiveness during the last century, devoid of accurate technic, lacking in purposeful attack on such hindrances to healing as are known to exist under certain circumstances, then the indications for the surgical treatment of ulcer as outlined by Dr Bevan may be very greatly broadened, provided the operation is to be performed by a surgeon of the ability of Dr Bevan

It is to be understood that an ulcer may be so large, broad and deep that healing may never take place

Roentgen-ray examination is likely to give a valuable clue to the extent of the pathologic process when unusual difficulties in healing are likely to be encountered

In Oxford Medicine and in the Nelson System I have summarized the results that may be obtained by maintaining an efficient neutralization of free hydrochloric acid in the treatment of ulcer

1 Pyloric obstruction is influenced as described
2 The pain is completely controlled
3 Excessive night secretion is controlled
4 Hemorrhage ceases, occult blood disappears from the stool
5 Perforation has not been known to occur after the second day on management in our service
6 The penetrating type of ulcer is rapidly influenced, the defect as shown by the roentgen ray relatively rapidly disappears If the defect is not definitely influenced during the first two weeks of treatment, cancer is thereby suggested or the defect is due to an old cicatrix or the conditions for healing are not good If a skilled surgeon is available, the patient should be operated on
7 Ulcers of the stomach and duodenum that failed to heal after gastro-enterostomy and other surgical procedures are relieved at once of the distress symptoms and eventually healing has taken place in many instances
8 Healing of ulcer occurs Necropsies on patients that have died of pneumonia or other intercurrent disease while on management have shown that the ulcer was healing or healed Operative removal of the ulcer bearing area for various reasons, a few months after treatment has been instituted, has shown on many occasions that the ulcer was healing or healed Accurate clinical observation extending now over a period of many years furnishes such evidence as may be obtained by observing that all symptoms of the disease have disappeared and not returned It is to be understood that a healed duodenal ulcer is likely to show a cap deformity More than half of all cases treated have been of the pyloric obstruction type with such definite evidence of obstruction as visible peristaltic waves, food retention, Sarcinae and cap deformities

CONCLUSION

Whatever the future may reveal as to the causes of ulcer and the influences that retard its healing, these results—as published in detail elsewhere—may be obtained by maintaining an efficient neutralization of free hydrochloric acid in the manner advocated In our service the method has been found applicable to the rich and poor alike After the four-week period of accurate supervision, the patient is able to take up his full work and continue with it, irrespective of its character, for the required time—a year or more if necessary Prepared chalk, magnesium oxid and sodium bicarbonate are relatively inexpensive drugs Except in those cases in which surgical treatment is clearly indicated, all agree that medical treatment should be given a thorough trial before resorting to surgical measures I am sure that if the medical treatment as outlined in Oxford Medicine is applied without modifying it to such an extent as to destroy its value, the necessity for surgical treatment of peptic ulcer will be very greatly reduced

THE RELATIVE RÔLES OF MEDICAL AND SURGICAL TREATMENT IN GASTRIC AND DUODENAL ULCER*

THOMAS R BROWN, M D
BALTIMORE

In presenting one's views as to the relative value of the nonsurgical and the surgical treatment of gastric and duodenal ulcer, one cannot help feeling the essential and inherent difficulties of such a discussion The enormous amount of literature on this subject of the past few years, with many conflicting articles trying to evaluate the various modes of therapy, some attempting to prove the wondrous merits or the hideous defects of some special operative procedure, or some selected diet or some drug, others trying to show that certain bacterial or neurogenic factors or vascular disturbances are the sole etiologic factor in the disease, others insisting that in the roentgen ray lies the sole hope of correct diagnosis, others that it is often unnecessary, and that the anamnesis or the utilization of certain special tests is the prime factor of importance in arriving at a true realization of the underlying condition, all show beyond peradventure the unsatisfactory and unsettled state in which this subject, so long studied by so many men of so many minds and from such different angles, still is, and how much both physicians and surgeons are in need of some rational basis of agreement as to the proper mode of attack in this group of cases

Certainly, as I look back through that long vista of years since the swaddling clothes of medicine first enfolded me, I seem to see, "as in a glass darkly," scattered through this vast and often arid desert, oases —appearing at regular intervals devoted to similar symposiums on the treatment of gastric and duodenal ulcer, where noted surgeons and intrepid clinicians battled valiantly for their special mode of therapy, and where, at the end of these Homeric conflicts, each left the field even more convinced than before of the omnipotence of his especial therapy, were it surgical or medical, and of the weakness and frailty of the lance of his opponent in these periodic struggles The reason for such dissatisfaction and for such uncertainty is not hard to find, for treatment without knowing the cause, without being sure that the symptoms are characteristic, and without being certain beyond reasonable doubt as to the diagnosis, must, of necessity, be unsatisfactory

ETIOLOGY

Let us for a moment, before discussing the question of treatment, mention briefly some of the moot questions in the field of etiology, symtomatology and diagnosis As regards etiology, the usual explanation is still that the immediate cause of the condition is the digestion of a certain portion of the mucosa by the proteolytic enzyme of the stomach, or its destruction by the corroding effect of the hydrochloric acid, but as to the contributory causes, the views are myriad Disturbance of circulation and consequent lowering of the vitality, as first suggested by Virchow, seems to me still to be the most plausible factor in many cases, but whether this is due to thrombi, or emboli, or to

* Read before the joint meeting of the Section on Surgery General and Abdominal and the Section on Gastro-Enterology and Proctology at the Seventy Third Annual Session of the American Medical Association St Louis May, 1922

constriction of blood vessels due to pressure or to reflex cause or to spasm or to a break in balance between vagus and sympathetic systems, it is often impossible to say

Certain experimental work in this field has shown that ulcers can be produced by occluding the vessels in various ways, but that this is not the only factor is shown by the fact that these ulcers heal spontaneously very rapidly, although their healing is distinctly retarded by chronic irritation from food, by an artificially produced anemia, or, according to some, by the administration of hydrochloric acid in considerable amount These three additional factors, that is, trauma, either external or internal, be it mechanical, chemical or thermal, anemia, notably chlorosis, and hypersecretion or hyperacidity of gastric juice—perhaps the terms are in reality synonymous—have many adherents Some believe, on the other hand, that qualitative changes rather than quantitative changes in the gastric juice play the fundamental role, others that the lack of antipepsin in blood or stomach wall is the prime cause

Many believe with Eppinger that a marked instability of the sympathetic and vagus systems is the underlying cause, others, that definite changes in the nerves themselves play a large role, and this has some experimental basis Disturbances in the motor sphere, peculiarities in the form of the stomach, such as ptosis or congenital malformation, functional or organic abnormalities in vascular and nervous systems, all of these have been regarded as factors of importance That the essential role is played by bacteria is insisted on by many, some believing in their specificity, others that they simply represent secondary invaders which inhibit healing and lead to chronicity As regards the former, many believe that the presence of specific streptococci is essential It is well to remember in connection with these various theories that the gastric veins are freely open to any substances coming from the spleen, that this may give rise to infectious emboli, as Gibson has insisted, and that "the anatomical distribution of the blood supply of the mucosa of the stomach is a prime factor in determining not only the location, but also the cause of gastric ulcer" as Hofmann and Nather have so beautifully shown, which supports the original view of Virchow that "ulcers are caused by embolism or thrombosis of the small vessels of the stomach, the congestion caused thereby leading to a diminution of the vitality of the tissues and digestion by the gastric juice," as well as the vagotonic and reflex theories of origin

The point always difficult to explain is, Why do ulcers become chronic? The striking feature of all artificially produced ulcers, whether due to freezing, to local trauma, to injury to nerve or blood vessel, or to other causes, is their tendency to spontaneous healing, and any one who has studied necropsy records must realize that this must happen in many cases in human beings as well—cases either diagnosed as ulcers or, more often, not diagnosed at all, owing to either absence or vagueness of symptoms Why some ulcers become chronic and intractable and others heal spontaneously is hard to determine, but it is probable that bacterial, chemical, traumatic or mechanical irritants notably, from the food or from its admixture with pathologic excretions or secretions of mouth, tonsils, accessory sinuses and stomach, or persistent and reflex gastric stimulation from elsewhere, notably the appendix, as Moynihan has so often insisted, or the instability of vegetative nervous system, which we call vagotonia may be the factors which convert the superficial acute to the deep chronic ulcer Perhaps, after all, this is the safest view to hold, that is, in the absence of a proved specific cause, an ulcer usually represents destruction of tissue by acid or by proteolytic enzyme due either to a localized lowered vitality secondary to some disturbance in blood supply, thrombotic or embolic, or to the constriction of spasm or pressure, and that chronic irritation of food, definite vagus irritation and bacterial invasion probably play the larger roles in preventing the ulcer from healing, and in tending to progression of the ulcerative process with its concomitant induration and cicatrization, although certain constitutional disturbances, notably anemia, may also play a role in certain cases

SYMPTOMS AND DIAGNOSIS

As regards symptoms, there is again nothing absolutely characteristic In some cases there are no symptoms Think, for instance, of the number of healed ulcers found at necropsies, in cases in which there were absolutely no symptoms during life which would make one suspect the diagnosis Think of the other cases in which the first symptom is hemorrhage or perforation, and the many others with such indefinite symptoms that diagnosis is not possible, and, on the other hand, the large number of cases with absolutely classic symptoms, and yet in which the subsequent course of the case or the operative findings reveal no ulcer In the last, of course, the symptoms are in reality due to some other cause, a diseased appendix or gallbladder, a gastric neurosis, or some instability of the nervous mechanism of the stomach or to its malposition, with consequent disturbance of motor or secretory functions or both In my experience, for instance, the typical ulcer complex is peculiarly likely to occur in gastroptosis with a high fixed pyloric duodenal region, when decompensating symptoms begin to appear It is this group of cases, incorrectly diagnosed, which has made so many surgeons regard with skepticism the diagnosis of ulcer on the part of the clinician, and has made them feel that, in many of the so-called cures by nonsurgical methods, ulcer, in reality, was not present at all, a group, however, probably equaled in number by those cases in which the patients are regarded by the surgeons as permanently cured because they leave the hospital with no symptoms, *and yet have a return of symptoms later*, the suggestive therapy associated with the operation, combined with rest, appropriate diet and hospital care, having led to a temporary complete disappearance of symptoms irrespective of the operative procedure

On the other hand, it must not be forgotten in this connection that, if the ulcer is very superficial, in other words is a real mucous ulcer or erosion, often it cannot be felt by the surgeon by palpation of the peritoneal surface, and, unless the stomach is opened, will not be recognized, and the latter procedure—opening the stomach—is hardly justifiable unless the case has been peculiarly intractable, or frequent hemorrhages have occurred, or pylorospasm with partial obstruction is a striking part of the picture

As regards the symptoms in detail, pain is often absent, sometimes atypical, but it is, of course, a valuable symptom, its relation to meals, its disappearance with the addition of food, often being extremely significant Periodicity of the attacks is, to our mind, the one most valuable clinical symptom, peculiarly likely

to occur in spring and fall, peculiarly unlikely to occur in summer—diagnostic points on which Moynihan lays special stress, and so beautifully brought out by Cohnheim's analysis of a large group of cases In all cases diagnosis must be made by a complex of findings vomiting, hemorrhage, effect on the appetite, sensitiveness to pressure or to percussion, dorsal pain points the finding of evidences of hyperacidity or hypersecretion notably of course, in the fasting stomach, the finding in the fasting stomach test of microscopic or macroscopic evidence of pyloric obstruction, the finding of occult blood in the stools, most important if the test is carried out with rigorous exactness, and findings from roentgen-ray examination

As regards hypersecretion, a few believe that hypersecretion always represents a potential ulcer, a view, we believe, that is not sound We must not forget that ulcer, especially of the duodenum, is not at all uncommon in children, that juxtapyloric and duodenal ulcers may all have practically the same symptoms and are much more common in man, and that ulcers of the lesser curvature are more frequent in women, have a much less clean-cut symptomatology and are much more likely to heal spontaneously

It is well to remember that, while practically none of the roentgen-ray signs are absolutely diagnostic, no examination is complete without a careful fluoroscopic and roentgenographic study, but the clinician is very unwise who puts his main reliance on this in reaching a diagnosis Roentgen-ray diagnosis, except in the hands of a very small group of real experts, is a frail reed to lean on as the sole diagnostic support We must not forget that filling defects, besides being due to definite organic lesion of the stomach wall, may represent anatomic peculiarities may be an evidence of spasticity, peculiarly likely to be met with in the so-called vagotonic group, or may be due to posture or to pressure, and are peculiarly likely to be met with in association with adhesions or as a reflex phenomena from disease elsewhere, notably the appendix When the roentgen ray can make a definite diagnosis, in many cases, probably in most, such a diagnosis could have been reached by other methods It is needless here to insist that frequent roentgenographic studies are important, and that one should not depend on one examination alone A persistent break in continuity in such examinations, or disturbance in the peristaltic wave often corresponding to the site of the pain on deep pressure is, of course, of extreme value, while modification in the peristaltic rhythm, and alternation of phases of fatigue and phases of hyperactivity are always suspicious In a series of 247 cases, previously studied by a most competent roentgenologist in which the diagnoses were verified by operation, Quervain found that a correct diagnosis was reached by the roentgen ray in 87 per cent of the gastric ulcers, but in only 54 per cent of the duodenal ulcers

In regard to the value of the occult blood test, it is well to remember that the benzidin test is far more satisfactory than the guaiac but that certain of the substances used in the treatment of ulcer, notably bismuth salts, and various absorptive mediums, can inhibit the catalytic action, and we will have a negative finding, notwithstanding the fact that bleeding still takes place With the utilization of all these signs and symptoms, with especial attention to a careful history of the case (and to me this is the one most important individual factor), especially the symptoms in the early phase before the picture has been blurred by late changes, such as increasing induration and adhesion development, with the thorough roentgen-ray study, and the careful study of the stool for occult blood and the gastric contents for both secretory and motor abnormalities, and with a thorough general physical examination, unquestionably we have done all that can be done in diagnosis in this field

That it is not completely satisfactory, however, is shown by the large number of incorrect diagnoses as demonstrated by the subsequent history of the case or by surgical treatment diseases of the gallbladder, renal crises or ureteral calculus, appendicitis, carcinoma, conditions caused by various forms of intestinal parasites, various neuroses, visceroptosis, the gastric crises of tabes, epigastric hernia, all of these present symptoms which in certain cases can make a real differential diagnosis almost impossible

TREATMENT

I have obviously far too little time to go into many of the details of treatment, medical and surgical, and therefore will call attention only to certain impressions, convictions, if you will, which I have reached from my experience in this field In the first place, it is singularly unfortunate that there has always existed and that there still exists the feeling that we must commit ourselves in all, or almost all cases of ulcer, to an exclusively medical or an exclusively surgical form of therapy—a point of view which is peculiarly unfortunate and absolutely false, because, in order that the treatment of these cases may be successful, each case must be studied individually, attacked as a definite entity, and treated accordingly, with utilization of every therapeutic measure at our command, including, of course, surgery, in a very considerable proportion of cases

In a disease of such varied etiology there must be a varied therapy, and the proper utilization of that therapy must be fitted to the case under study, be it regulation of life, dietetic suggestions, the use of drugs, the application of various forms of physical therapy or the utilization of one of the various surgical procedures, and must of necessity be determined in each case individually To hold a brief for any special therapeutic procedure, be it the employment of a rigorous scheme of diet, or a certain drug, or a small bucket on the end of a rubber tube, or a special operative method, is unscientific and unsound and unsafe Each case must be regarded individually, each case has its special features in etiology and symptomatology, and in each case these must be carefully considered in planning the appropriate treatment

Let us briefly touch on some of the points of importance in the treatment of these cases as I have seen them

As regards planning the special treatment, I have to reiterate that I have been helped considerably by careful analysis of the patient's history, the attempt to elucidate factors which seem to play a part in calling forth the syndrome and to combine this with a most complete general physical examination in order to determine other factors of equal importance, the presence or absence of focal infection, the condition of the circulatory apparatus and of the nervous system, and the presence or absence of psychic factors in the case, in other words, the attempt to get every possible help from the history, from the physical examination, and

from special tests before attacking the special problem of the individual patient

If it seems wise to attack the problem first without surgical help our main reliance must be on rest and diet. Rest does not necessarily mean rest in bed, although in most cases such an absolute rest is important, but most people forget that the rest of the mind and of the nervous system is of as great, and sometimes greater, importance than mere bodily rest, as disturbance in the psychic sphere may produce far more marked secretory and motor disturbances than even active exercise. On the other hand, if bleeding is not taking place and the symptoms are relatively mild, very often for various reasons an ambulatory treatment will be more successful than absolute rest. If the symptoms are acute, if bleeding is present, rest is essential, and it is our most valuable therapeutic aid. In these cases, whether it is for two weeks, four weeks or six weeks must depend on the individual conditions, but, unless we can promote psychic rest at the same time, our efforts sometimes go for naught.

The principles of diet are relatively simple. From the days of Leube and Ziemssen, it has been recognized that diet must be nonirritating, must furnish a sufficient number of calories, must call forth as little as possible gastric secretion, and yet must neutralize as much acid as possible. It is, therefore, quite obvious that certain diets will better satisfy certain of these requirements, other diets, other requirements. If the patient is strong, or if bleeding is marked, a few days of absolute starvation with a rectal drip to relieve thirst and to lessen acidosis is advisable. Again, in robust patients, we can give diets of lower caloric value than in those that are depleted, and quite obviously need building up. Whether we choose a cereal-carbohydrate diet, a milk diet, an olive oil-gelatin diet, a pure diet or a mixture of soft foods must depend on the individual patient. Some do well with one, some do well with all. The proportion of cures, if one can judge by statistics, seems to be about the same with any of the special diets, but I wish to reiterate: do not confine yourself to one special dietetic scheme, try to suit the individual findings and the individual tastes of your patient. It is far better to satisfy a patient with cereals than to disgust him with an exclusive milk-cream diet, and vice versa, while often a combination of both is better than either.

Whether to feed at one hour or two hours or at even longer intervals is again a question which must be decided in each case. The important thing is to prescribe the diet which will bring the best results in the quickest time, and then not forget that the treatment must not end with the cure, but that the patient must follow careful dietetic directions, the diet, of course, being in most cases a relatively broad one, yet always within the limit of his capabilities, for a long period of time, sometimes for a year or more, sometimes, in the chronic cases, practically indefinitely.

If the patient does not respond to rest, simple drugs and diet, and local applications of heat or cold, whichever seems the most effective, within ten days' or two weeks' time, especially in cases which have had a long history, it is always wise to ask ourselves the questions, Is the diagnosis of ulcer correct? and, If it is correct, are we not also dealing with definite complications, such as marked induration and cicatrization and development of adhesions? Whether we use alkalis or not is again largely a question of individual feeling. Most patients get along better with them, and recent work seems to show that if properly administered they not only neutralize the acid formed, but distinctly inhibit acid secretion. On the other hand, there are certain cases in which alkalis, especially the carbonates, do unquestionable harm. Again, in regard to belladonna, if we have evidence that one, at least, of the factors in the ulcer picture is an irritable vegetative nervous system, with unstable balance between vagus and sympathetic, it is the most valuable drug we have, but only if given in maximal doses.

With the foregoing treatment, we can really cure a large number of acute cases, we can definitely relieve the symptoms in many of the chronic cases, and if the patient is conscientious in carrying on the proper after-treatment, may have a symptomatic cure, but we must always realize that the mere cessation of symptoms does not necessarily mean cure, and until we are able definitely to attack the causal factors, we cannot honestly say we have cured the chronic cases. An ulcer scar, if deep, is a point of least resistance, which may produce no symptoms under ideal conditions, but may play a very potent role in disturbing motor and secretory functions if these ideal conditions—psychic, dietetic, physical—are interfered with, and in life, alas! as it is lived now, it is practically impossible to avoid this. As long as an indurated area or a callous scar remains, we have the potential basis for further trouble, and this is, and must be, an important reason for the surgical attack on this group of cases.

It is, of course, obvious that in perforation or gross obstruction which represents organic stricture, and not spasm or edema, or the tendency to repeated hemorrhage, or malignant change, surgery is the only rational procedure, and it seems to me just as obvious that for the acute superficial ulcer, medical treatment is the only procedure to be considered. But in that large group of cases of chronic ulcer without obstruction, without repeated extensive hemorrhage, we must always realize that, up to the present at least, neither method of treatment has been sufficiently successful to warrant the exclusion of the other. Of course, if you believe with some that every ulcer is a potential carcinoma, operative treatment is the only treatment, but I think this belief is not well founded. It seems to me that it is very safe to preach the doctrine that, in these chronic cases without need for immediate surgery, it is far safer to try medical treatment first. Little time is lost and no harm is done, the second state of the patient is no worse than the first, and it is possible that a symptomatic cure may be obtained. But if such treatment conscientiously applied, skilfully given, with a sufficient period of time to test its efficacy, does not yield results, I feel that the patient, even in the present status of surgery, should be treated surgically and not medically. Before making this decision, however, it is wise to try every one of the factors mentioned above to see whether good results can be obtained. Improving the general condition is one of the most potent of these factors, and nothing demonstrated more strikingly the importance of systematic exercise and freedom from responsibility than the marked improvement met with in many cases of absolutely definite ulcer among men who were in active service during the war.

In treating the complications of ulcer, I feel that the treatment of extensive hemorrhage should always be medical, that the appearance of tetany after the pre-

liminary treatment with calcium acetate or ammonium chlorid given intravenously should call attention to the need of immediate surgery to relieve the obstruction, and that the only justification for duodenal feeding is vomiting which cannot be controlled by other means

In discussing treatment by surgical means, we must always compare the severity of the symptoms, their frequency, their alleviation, if not cure, by medical means, and the effect of the patient's symptoms on his happiness and his work, with the probable results of surgical treatment After all, only two forms of benign gastric disease have a vital indication for operation almost complete pyloric stenosis and frequently recurring hemorrhage, in all other cases the need of operation is relative, not absolute

That surgery has not been universally successful in many of these cases is shown by the shift of surgical opinion as to the operation of choice, gastro-enterostomy, pyloroplasty, cauterization or excision, resection, Polya operation, all of these having their adherents At the present time, not one of these operations will bring about a condition approximating the normal, each is liable to development of certain post-operative complications jejunal ulcer, vicious circle, recrudescence of ulcer symptoms, intestinal indigestion after gastro-enterostomies, and the possibility of obstruction or of the formation of adhesions to a greater or less extent in all the other cases, as witness the many patients returning for a second or even a third operation In this field, the technical difficulties of many of these operations are great, notably in pyloroplasty, although, if properly performed, I believe it is the best operation Each operation will leave behind something abnormal in the stomach or duodenum which, given other factors of disturbance in gastro-intestinal mechanism, may lead to definite reflex disturbance in the secretory and the motor spheres or in the metabolic gradient, if you will

Certainly, it is well to remember all of these factors before committing the patient to surgical therapy, and yet, in my experience, in the chronic group of cases, even without obstruction, surgery has been more effective and more permanent in its results in the majority of cases than medical treatment, notably in cases in which pyloroplasty, resection or the Polya operation has been done To me, gastro-enterostomy has always seemed peculiarly unphysiologic, I have rarely seen cases, except those of almost complete pyloric obstruction, in which it has been absolutely successful, and gastro-enterostomy has never seemed to me the operation of choice, but the operation of necessity

It is hardly worth while reiterating here the fundamental importance of careful postoperative treatment in order to prevent the formation of adhesions, the development of a new ulcer, or the recrudescence of the ulcer which we have not been able to remove The avoidance of gastric and intestinal symptoms must be dependent on careful postoperative management, and this, I feel, can be far better directed by the clinician than by the surgeon Many potential successes have been converted into absolute or complete failures by the lack of this cooperation in the after-care of surgically treated cases, and there is no condition in which an ulcer cure is more plainly indicated than after surgical removal of the ulcer It seems to me that it is a very poor clinician who will refuse the help of the surgeon in this group of chronic cases and an equally poor surgeon who will not utilize the clinician's knowledge of dietetics and physical and drug therapy

It is interesting to note that practically the same percentage of cures is claimed by the followers of each special scheme of diet as by the followers of special surgical procedures Each must be deluded as to these figures Certainly from 75 to 90 per cent of ulcers are not really cured in the true sense of that word by either medical or surgical procedures Our clinics and consulting rooms are filled with patients suffering from recurring symptoms after medical treatment, and with patients that return with the same or different symptoms after surgical therapy

SUMMARY

We have tried to show certain of the difficulties inherent in this subject, especially as regards treatment, but also as regards etiology, symptomatology and diagnosis Certainly, any one who approaches this subject with an unbiased mind cannot help feeling more dissatisfied than satisfied at the picture presented, but there are, I feel equally sure, certain conclusions that we are justified in drawing from this survey, based on proved facts in etiology, symptomatology and diagnosis, on the experience founded on the careful study of many hundreds of such cases over long periods of time and on the many lessons learned from our successes, and especially from our failures, always remembering that with such a probable multiplicity of etiologic factors, there cannot be one, and only one, successful mode of treatment Relative rest, a non-irritating but ample diet, the utilization of certain simple principles as to physical therapy and simple medication, with the subsequent inculcation in the patient of proper habits of living, not only as regards diet but also as regards the proper attitude toward his environment, these are the fundamentals of medical therapy, in addition, of course, to the elimination of factors that may play a large etiologic role, notably focal infection and diseased conditions in other portions of the abdomen

Individualize your cases, do not treat all cases alike, remember that what is one man's meat is another man's poison Some will do well on milk and cream, others on a diet rich in carbohydrate, but relatively poor in protein In some hourly feedings are beneficial, in others longer intervals bring better results Never fail to remember that practically the same estimated proportion of cures—all, incidently, far too high in my opinion, because of the improbability of correct diagnosis in certain cases and the impossibility of thoroughly following up many cases—have been reported by the violent partisans of each special dietetic schema, which should suggest to us that frequent feeding with any suitable nonirritating diet is the great desideratum, if the patient is given, in addition, proper bodily and mental rest Remember that many cases are cured spontaneously, and will be cured whatever the diet, and also, alas! many others are not cured by any of the diets chosen Never forget the important contributory role that psychogenic and neurogenic factors play in some cases, unquestionably a larger role than mechanical irritation of food, and that the mitigation and diminution of these factors will do more than any one thing in bringing about a symptomatic cure at least or in preventing a relapse, and never forget that far too little attention has been paid in the period of after cure to exercise and other forms of physical therapy to improve the nutrition of the patient

It seems wise that all acute ulcers, except, of course, those with symptoms of perforation, be tried first with

medical treatment, for the success of such treatment in this group of cases is large, and it seems wise also that, in the present state of surgical therapy, even in the chronic ulcers, except those with marked organic obstruction or with a history of repeated hemorrhage, nonsurgical treatment be tried first, not because we can produce a true cure, because in the case of the deep callous ulcer with induration and cicatrization, cure, in the true sense of the word, cannot be obtained by medical means, though often we can bring about a disappearance of symptoms and a symptomatic cure, but because it seems fairer to the patient than immediate recourse to surgery, with its multiple possibilities of early and late postoperative complications

If, on the other hand, medical treatment does not bring about relief, it is foolish not to give the patient the possible benefit of surgical therapy, with resection of the ulcer, and as close an approximation to the normal physiology as possible, in the hope that adhesion formation and disturbance of gastric function will be reduced to a minimum after the operation After all, chronic callous ulcer is fundamentally surgical, and would always be surgically treated were it not for these many postoperative complicating possibilities It is well to remember that many failures are not referable to the operation as it is conceived, but as it is performed, for the technical difficulties of this work are great, and the really capable surgeons in this sphere none too numerous

There are, of course, certain encouraging aspects of this subject Even if we do not know the fundamental cause of ulcer (if there is such a cause), we have, at least, added largely to our knowledge of certain contributory etiologic factors The many spontaneous cures as shown by pathologic reports, the number of cases of undoubted recovery under medical treatment, the definite realization that certain of these conditions never, in the strict sense of the word, become chronic, that is, the lesions do not become indurated, but remain superficial, the prolonged periods of perfect health between the periodic outburst of symptoms in many cases of duodenal ulcer, the great improvement in surgical technic, with its minimization of avoidable complications, the addition of operations which attempt a closer approximation to the normal physiology, and certain additions to our diagnostic methods, notably the study of the stool and roentgenologic studies, all of these show beyond question that there has been some progress in this field

On the other hand, when we think of the investigators who have struggled, in the main unsuccessfully, to clear up the fundamental question of etiology in this group of diseases Virchow, Rokitansky, Cohnheim, Pavy, Ziemssen and literally hundreds of others, when we think of the ever present difficulty of making a correct diagnosis and the many moot points in symptomatology, and when we remember the great number of complete and partial failures after treatment both medical and surgical, we must, I believe have a feeling of dissatisfaction rather than of satisfaction at the present state of this subject The unsolved problem is still the problem of many years ago Why does not the spontaneous ulcer of man heal as rapidly as the experimental ulcer of animals, and why does it show such a tendency to the progressive changes that lead to chronicity? We are still unable to answer to our complete satisfaction the two questions, Why is an ulcer? and When is an ulcer? Could there be a more discouraging admission as to our dissatisfaction with the present status of ulcer therapy than Moynihan's recent suggestion of jejunostomy with subsequent complete rest of the stomach for many months in certain cases except perhaps it be for the apparent demand for these periodic and inconclusive symposiums?

We are still waiting for a Moses to lead us out of the wilderness, for some one to show us at last what the fundamental underlying factors are so that we can utilize that best of all therapeutic measures, preventive therapy, but, until such a promised land is reached, we must of necessity be compelled to utilize the means at present at our command For these measures to give the optimum result, we must realize that the blind following of any one method of therapy can never spell progress, that the patient must be the first consideration, that each case must be studied and treated individually, that, in the treatment, that form of therapy must be employed which is best suited to his special needs and this can only be brought about by a far closer cooperation between clinician and surgeon in the study as well as in the treatment of these cases, and that, as a result of this cooperation, which will redound not only to the benefit of the patient but also to the benefit of surgeon and physician, we shall no longer talk of medicine *versus* surgery, but medicine *and* surgery in the treatment of gastric and duodenal ulcer

19 West Biddle Street

ABSTRACT OF DISCUSSION

ON PAPERS OF DRS BEVAN, SIPPY AND BROWN

DR J M T FINNEY, Baltimore The subject has been covered so well by these papers that I find myself at a loss in attempting to discuss them About all I can do is simply to emphasize a few of the more important points In discussing the management of gastric ulcer, it must be admitted that the prevailing feeling is one of dissatisfaction, with both the medical and the surgical treatment We are still short of saving 100 per cent of cases and the goal is 100 per cent The reason is the lack of certain knowledge as to the etiology of ulcer and our lack of ability to make a diagnosis of ulcer with any degree of certainty Even with the aid of my skilled medical colleagues, I find myself sometimes unable to make a definite diagnosis of ulcer either duodenal or gastric Furthermore, sometimes I find myself very much embarrassed when I have the stomach right before me to tell whether there is an ulcer Even when I have opened the stomach in the course of a pyloroplasty, I find myself still more embarrassed to tell whether there is an ulcer—with the mucosa right before me I heard Dr Pool say that in case of doubt he did a gastro enterostomy to see whether there was an ulcer or not That encouraged me greatly The prevailing method of treatment in the vast majority of cases of ulcer has been gastro-enterostomy, so that many surgeons invariably think of gastric and duodenal ulcer and gastro-enterostomy almost synchronously That is one of the greatest reasons for this feeling of dissatisfaction that exists today with the treatment of gastric or duodenal ulcer We have been generalizing too much on insufficient data We have been operating without really sufficiently definite indications for operation I would urge that we endeavor to unravel the mystery which exists in regard to the etiology and to establish a satisfactory treatment whether medical or surgical or both, of gastric and duodenal ulcer I have tried every accepted method of surgical treatment and I am still dissatisfied with the results I have felt that the best thing to do is to extirpate the ulcer I have tried the excision method advocated by Moynihan, with really satisfactory results, but that is a big operation, an operation that seemed almost too extensive to be performed as a routine procedure. I have satisfied myself that gastro-enterostomy per se offers no guarantee of a cure of the ulcer I have done simple pyloroplasty by my own method and by other methods and I have satisfied myself that pyloroplasty by itself offers no

sure guarantee of a cure of ulcer Therefore I now try to excise the ulcer through a pyloroplasty excision suggested by me about twenty years ago So far I have not had enough cases to convince myself that there is enough merit in that operation to advocate it So far there has not occurred a death or a recurrence My experience up to the present time convinces me that in the vast majority of cases it is feasible to excise an ulcer situated within 2 inches (5 cm) of the pylorus, on either side, through a pyloroplasty incision, with comparative ease and with great satisfaction to the patient I do not advocate that operation but I believe it offers something for us to think about My experience convinces me that when we can devise a method which will allow us to mobilize those parts sufficiently, the proper solution of this question will have been reached

DR FRANKLIN W WHITE Boston The opinions of medical and surgical advocates on this subject are getting closer and closer together and we find that whatever differences of opinion there have been in the past, they were largely due to the different types of case seen by the physician and by the surgeon Virtually every ulcer is first treated medically, and out of this big group is selected a small group of more serious, resistant, complicated cases with stenosis or recurrent hemorrhage which go to the surgeon The treatment of ulcer is not medical or surgical, but a combined treatment, one method being employed as far as available and followed with the other method We get good, permanent results with real medical treatment in a large percentage of cases Dr Bevan said about 90 per cent which leaves only 10 per cent for the surgeon This shows the heavy medical responsibility of the family physician and the internist for the treatment of most of the ulcers Dr Mayo's argument for the saving of expense and loss of time to the wage earner by surgical treatment is not a very strong one Medical treatment is ambulatory, as a rule Only a small group of the more seriously ill patients need a rest in bed for a week or two at the start, so that there is little economic loss in medical treatment, unless there is a recurrence Recurrence is preventable, as a rule, or easily controlled, in the uncomplicated cases The essential difficulty in medical treatment is not the early control of symptoms, such as pain vomiting and bleeding, but the carrying out of the regimen when the patient is symptom free Failure to do this has discredited medical treatment, and it has been a frequent cause of recurrence and failure of the ulcer to heal It is a matter of patience to heal a chronic ulcer it takes time This should be explained to the patient in advance, so that he will understand what is expected of him If recurrence can be avoided medical treatment is the method of choice in uncomplicated cases The patient must always make some sacrifice in taking either treatment on the one hand the sacrifice of a month or two for surgery and convalescence the time in the hospital the cost and moderate risk on the other hand with medical treatment, the moderate sacrifice of tastes and habits, but for a much longer time the observance of better hygiene, giving up tobacco and coarse foods and overcoming bad habits of eating The change of diet is not for a lifetime, but for a year Most patients with uncomplicated ulcer, the 90 per cent group, prefer medical treatment but naturally in the serious cases, the 10 per cent group the patients, when the situation is fairly put to them usually prefer surgery Another point is the importance of medical treatment for quite a long period after the operation The patient, and often the surgeon also will probably feel that after the operation he is good as new, and he begins to boast about what he can eat As a matter of fact there is a real necessity for some care in diet for months afterward The best results are obtained by the hearty cooperation of physician and surgeon

DR WALTER C ALVAREZ San Francisco Whenever one of my surgical or medical friends says to me that he can cure all cases of ulcer I like to tell a little story of St Peter and St Paul They were sent to earth to make a little report Lunch time arrived and they went into a cafe to eat When the time to pay came Paul said I will pay" and Peter said 'Oh, no, I will pay' As they could not agree, the waiter brought a little box with dice Peter shook the dice and said a few words and rolled out five sixes Paul shook them and said a few words and rolled out five sevens and Peter said Now Paul, no miracles between friends" Although I am a clinician, I must admit that I have more faith in the surgical than in the medical treatment of ulcer It is easy enough to cure many of these patients medically, but the trouble is, they will not stay cured The tendency to relapse is too strong I believe that people seen in the first one or two attacks should be given the chance to try a medical 'cure" unless they present certain features, such as marked gastric stasis tendency to perforation, or a suspicion of carcinoma which make them fitter subjects for surgical attention But, what are we to do with the many patients who cannot afford a strenuous and expensive 'cure' in a hospital especially when there is a 'big chance that the ulcer will return in six months or a year? Let me offer a suggestion from my experience Years ago, I thought an ulcer cure without rest in bed did not amount to much, but I have since discovered to my surprise that I can get as good results in ambulant cases as I used to get in the hospital The best cases for medical treatment are those with fairly recent duodenal ulcers Their main symptom is pain, relieved by the taking of food Insist on their taking some food every two hours and in uncomplicated cases you will give immediate and striking relief A man who is up and at work needs a liberal diet so let him have three square meals Forbid him the coarser vegetables salads fruits bran and all foods with pits seeds and skins In the morning have him mix up a pint and a half of milk, a half pint of cream and the yolks of four eggs Some of this eggnog should be taken to the office in a vacuum bottle so that he can take a glassful every two hours between meals Some should be taken also on retiring and a glassful should be beside the bed in case he wakens during the night Many of these people fatten on this diet and feel fine Those who are not helped will generally do better in the hands of a good surgeon Others are perfectly comfortable so long as they stay on the diet but develop symptoms again when they stop They also may have to be subjected to operation Remember that the essential thing is the giving of food so soon after each meal that the hunger pains cannot develop

DR. ALBERT J OCHSNER, Chicago My observations have had very much the same scope as those of Dr Bevan and Dr Sippy In other words, my clientele represents a group of people who are likely to consult me when they have some disease from which they have not recovered under the treatment of their local advisers I have had the opportunity of observing thousands of gastric and duodenal ulcers both from the medical and from the surgical standpoint When I looked up my series last it had far exceeded a thousand cases that I have treated surgically, and I have found that there are at least four patients that will recover permanently, under proper internal treatment to every one that requires surgical treatment I have had the opportunity to see the late results in the cases observed because I am constantly in contact with the same group of people The papers presented this morning outline the best possible medical and surgical treatment of gastric and duodenal ulcer What Dr Bevan and Dr Sippy said covers general practice What the Mayos have said gives the very best of surgical practice in cases that have failed after going the limit of medical treatment Almost all of the failures in treatment of the internist ultimately come to the surgeon If the surgeon is not in contact with patients who are being successfully treated by the internist, he comes in contact only with those patients who have been cured five or six times medically and at last have to be cured by surgical operation He does not come constantly in contact with the four patients out of five that have permanently recovered under the Sippy treatment or that which Dr Alvarez has just described Virtually every case in which the surgeon has failed to obtain a cure is bound to come to the internist Consequently he has no judgment about the large proportion of cases that have satisfactory results from surgical treatment The reason that certain persons have such extraordinary results under medical

treatment is that the patient will do what his physician instructs him to do Recurrences are prevented in a large percentage of cases I have found, in watching these cases of recurrent ulcer that had been treated medically that in every instance something has happened which stirred up a latent ulcer, which would not have been stirred up if the primary directions had been carried out We know from experimental observations in animals that it is almost impossible to keep a gastric or duodenal ulcer open No matter what you try to do, almost all of them will heal Why should they not heal under similar conditions in the human? Take a dog and cause a gastric ulcer in his stomach and try to feed him bones He will not eat them He has too much sense, humans have not Postoperative jejunal ulcer has been mentioned a number of times this morning In every case in which I have operated on a jejunal ulcer following a gastro-enterostomy, I have found that the anastomosis was not made at the lowest point of the stomach, usually through some mistake The surgeon tries always to get the lowest point, but for some reason he may fail to get it If the anastomosis is made too high, there will be an accumulation of acid or of decomposing gastric contents, which corresponds to the condition which produced the duodenal ulcer in the first place We should also remember that, following any form of surgical treatment for gastric or duodenal ulcer, we have a badly impaired machine Consequently if you abuse that machine dietetically after the operation you are bound to have trouble It is as important to insist on a proper diet after surgical treatment as it is during medical treatment

DR FRANK SMITHIES Chicago The chief satisfaction that has come out of this discussion is a general admission of the fact that we have not advanced very far either nonsurgically or surgically, toward the permanent relief of certain types of ulcer of the stomach and duodenum Virtually everything that has been talked over this morning, with the exception of certain frills in surgical technic was discussed by the ancients, and they expressed in almost precisely the same language as has been used here this morning their puzzlement respecting the etiology of peptic ulcer and admitted that they were defeated in attempts toward securing permanent relief from certain types of ulcer The time has come for a revaluation of certain known factors in the causation, the continuance and the healing of peptic ulcer From these discussions, the knowledge derived from the experimental production of ulcer and from the results of treatment of patients carefully followed up certain significant facts are revealed Among these I would mention the fact that all types of treatment have had the same influence toward the permanent relief or cure of proved peptic ulcer The ulcer that we cure readily by nonsurgical treatment is usually the ulcer about whose existence we have been in doubt The ulcer that we cure most permanently by surgical treatment is the ulcer that is most complicated In other words the treatment in both instances has been directed toward what might be called the complications of a certain type of disease, which disease has certain gastric manifestations both symptomatically and pathologically It would appear to me that the time has come for us to recognize that very likely with peptic ulcer either gastric or duodenal, we are not dealing with a disease in the stomach or duodenum *sui generis,* but with a type of complication of systemic disease in which disease the stomach or duodenum has become involved Such disease may be initiated by a wide variety of systemic upsets It thus follows that numerous etiologic factors can be brought forward in ulcer, that there are different types of pathology associated with it and there is a wide variation in reports regarding the results of treatment So general is the dissatisfaction throughout the country as to the results of ulcer treatment that it almost becomes the duty of these combined sections to appoint a committee to study into this question It occurs to me from study of the so-called etiologic factors in ulcer that we are not going to make any permanent therapeutic advance until we recognize that what we are now doing in the treatment of ulcer is merely treating a local gastric complication and not a disease which is systemic in type, and which may be initiated by a wide variety of agents

DR ROBERT C COFFEY, Portland, Ore Too much pessimism has been shown here No condition responds to treatment more readily and more accurately than duodenal and gastric ulcer Dr Sippy has developed the best and most rational system for treating a given lesion medically I believe that Dr Sippy has given us the best conception of the agencies required for treatment, either medical or surgical I wish I could be as positive and agree with Dr Bevan If I were in the Presbyterian Hospital and had the association of Dr Sippy I am sure I would have the same opinion he has The great majority of medical men who claim to be using the Sippy treatment do not get the results On the other hand if the only surgeon available were the one who has the fatalities, I would want medical treatment But if I could go to the best surgeons, that would be a different story I believe with Dr Sippy that it is a medical disease primarily, a bacterial disease perpetuated by chemical agencies, and that the treatment should be primarily chemical I do not believe in the radical operation The results were better in my early cases of gastric and duodenal ulcer in which I did not excise the ulcer than where I excised it Of course, if you suspect that a gastric ulcer is going to be malignant, or if it has a large crater which cannot be collapsed in any way, operation is indicated The whole question of dealing with these cases is that we must perfect our technic no matter whether we treat medically or surgically We should give the medical men the first chance If they are competent they will get a good percentage of cures In my last 119 cases there has been one death after gastro-enterostomy alone That is not a mortality which should bother us It is no greater than that with medical treatment The majority of cases will be better treated by that method My plan is to do a gastro enterostomy and then await results Excision should be very carefully guarded and watched I believe, too, that the complete removal of the pylorus is better treatment because the other does not cure the ulcer Pylorectomy as done now is undoubtedly a better plan of treatment

DR SEALE HARRIS, Birmingham, Ala Dr Alvarez brought the Bible into this discussion, and I think I can quote a passage from the Bible which fits most of the patients with gastric and duodenal ulcer It is about the woman whom Christ healed at the well, who "had suffered many things at the hands of many physicians until she had spent all of her substance and she was neither better, but rather grew worse" I think that most of the ulcer patients who come to us have gone through that period The reports of the Mayos a few years ago stated that the average length of time that their ulcer patients had had symptoms was more than nine years A report of 1,000 cases studied by Finney and Friedenwald showed that their patients had symptoms probably due to ulcer for ten years In a study of 500 of my cases I estimated that they had had ulcer symptoms for five years The most important problem in handling ulcer patients is to make an early diagnosis and that depends to a great extent on the diagnostic skill of the gastro-enterologist or the physician and also on his interest in the subject I had an experience during the World War that illustrated this pronouncedly We were supposed to have a gastro-enterologist assigned to each of the army hospitals In inspecting these hospitals I went first to the hospital at Camp Devens There a gastro-enterologist was placed in the ward and he had about fifteen cases of gastric ulcer, which were proved by roentgen ray and occult blood in the stool and other symptoms and signs I then went to Camp Dix, where the gastro-enterologist had been assigned to drill physicians to teach them to be soldiers There was only one ulcer case in the 40 000 soldiers there I went to Camp Green, and there the gastro enterologist had about twenty cases of ulcer in the hospital There were very few cases of ulcer operation in soldiers during the World War Textbooks will have to be rewritten before many cases of gastric and duodenal ulcer diagnosis will be made early The triad of symptoms, pain vomiting and hemorrhage, is usually considered pathognomonic in ulcer They are all late symptoms, usually not always In my series of cases less than 10 per cent of the patients had hemorrhage, and nearly all had symptoms of ulcer over a period of a number of years before the hemorrhage occurred Pain may never be present in ulcer as

surgeons know who operate in cases of perforation of the stomach in which the patient had no symptoms until the perforation occurred One diagnostic point I should like to bring out is the syndrome of the so-called chronic appendix About 50 per cent of patients with ulcer who come to me have first had an appendectomy with a small incision in the right lower quadrant of the abdomen The surgeon who operates in a case of chronic appendicitis, so called, with a small McBurney incision in an operation of election, not an acute case, and does not extend that incision up to explore the duodenum, the stomach and the gallbladder, is very remiss in his duty to his patient We shall come nearer approaching the 100 per cent cures when we make the diagnosis early Ulcer is first a medical case, and the number of cures depends to a considerable extent on the technic of the physician The best diet in these cases is my modification of the Lenhartz diet, but we owe a great debt to Dr Sippy for his effort to alkalize the contents of the stomach in the treatment of ulcer

DR J SHELTON HORSLEY, Richmond, Va Dr Brown has struck the keynote of the whole thing He says that in the treatment of gastric or duodenal ulcer we must have medicine *and* surgery, not medicine *or* surgery Almost all acute cases should be treated medically Postoperative cases so far as diet is concerned, should be in charge of a medical man, and, after the patients leave the hospital they should be in charge of a medical man The object of all surgery should be to extirpate or correct pathologic conditions and to restore physiologic conditions as far as possible With this in mind, gastric and duodenal ulcers will fall into definite groups First, simple ulcers in the first inch of the duodenum or near the pylorus best treated by pyloroplasty with excision of the ulcer I do the pyloroplasty I described in 1919 which consists of incising the duodenum not more than 1 inch from the pylorus and making an incision into the stomach at least double the incision into the duodenum The wound is sutured vertically This pyloroplasty is simple, exposes the pyloric portion of the stomach well does not require mobilization of the duodenum and is accompanied by excision of the ulcer If there is marked destructive stenosis or a large ulcer with extensive leukocytic infiltration the disease has gone too far for physiologic restoration, and pyloroplasty is not indicated Gastro enterostomy then gives the best results When the ulcers tend to recur or malignancy is suspected pylorectomy by the Billroth I method, or by the Polya operation, should be done Pylorectomy should not be a routine primary operation for ulcer when pyloroplasty or gastroenterostomy, which are less dangerous may give as good late results If there are adhesions of the duodenum particularly to the gallbladder, that gallbladder should be removed (and the stump should not be drained) at the time of the pyloroplasty This also extirpates a possible focus of infection If there are adhesions elsewhere, gastro-enterostomy should be done As food goes out the normal outlet tugging on adhesions by peristalsis will produce somewhat the same pain as is produced by the ulcer In doubtful cases when it is difficult to decide between pyloroplasty and gastro enterostomy, the former operation should be done, because it is easier and safer to do a secondary gastro-enterostomy than to uncouple the gastro-enterostomy and also do a pyloroplasty

DR ARTHUR DEAN BEVAN, Chicago I have been interested and instructed I think however, that altogether too pessimistic a tone has prevailed We have made great progress in the last twenty years Twenty years ago when a man had a duodenal perforation he died almost invariably Think of the hundreds of lives which have been saved, with perforating duodenal ulcers, in the last twenty years by the knowledge that we have obtained since that time the knowledge that enabled us to recognize this clinical picture and to operate immediately and close the leak and save the patient's life In the last twenty years the medical men have contributed knowledge of great value and have demonstrated their ability to cure these ulcers under medical management I think that is as definite as that two and two make four From now on there will be a stronger tendency for all of us to recognize more fully than we have before the value of medical management and the indications of the different surgical procedures that have been evolved In regard to the operation on the ulcer itself, when the abdomen is opened, one should not forget that probably 20 or 30 per cent of these ulcers are not palpable even when one sees the stomach and duodenum The majority of these, however, become tangible when the duodenum and stomach are mobilized, many of them will be plastered to the pancreas In a good report from the Heidelberg Klinik of 240 resections for duodenal and gastric ulcers it is stated that 30 per cent could not be seen or felt by the surgeon when he opened the peritoneal cavity, the majority were found only after he had mobilized the stomach and duodenum We are making progress, we have made progress that is really worth while, and by this sort of combined research between medical men roentgenologists and surgeons we will place clinical research on the highest plane of all medical work that is being done in medicine

DR CHARLES H MAYO Rochester, Minn I am very glad that Dr Coffey has discussed this note of pessimism with regard to the cure of these patients It would be unfortunate to have a note disseminated since the majority of these patients are eventually cured either medically or surgically There is a remarkable difference between hyposensitive and hypersensitive stomachs Gross ulcers may produce only slight symptoms and some of the patients who are told they have ulcers are complaining not of spells of remissions and periodic attacks but of constant severe pain and they strongly urge that some kind of operation be done Such cases must be investigated carefully Dr Sippy is to be congratulated in having done so much to organize medical treatment of ulcer in this country and it is along the line of his teaching that we have been carrying on the work Certainly it would be a crime to subject some of the medical cases to surgery, because of the long time between attacks and the mildness of the attacks With regard to the patients with achlorhydria and peptic ulcer It is possible that some of these patients had achlorhydria before they developed ulcer Others have a small amount of acid, not to exceed 8 or 9 per cent Such patients are getting the Sippy treatment, but it is not curative With regard to the medical after-care A lot of patients after gastro enterostomy, need no care at all, but I believe that most of them should be directed to their medical attendant for future care if they need it

DR BERTRAM W SIPPY, Chicago While it is true that the results of both the medical and the surgical treatment of peptic ulcer as applied today are very far from ideal, we must not lose sight of the fact that sufficient knowledge of the disease and its treatment already exists to combat it successfully in all but the exceedingly exceptional cases This can be said of relatively few other diseases of serious nature It is commendable to express dissatisfaction regarding our knowledge of peptic ulcer, but there is scant excuse for the general tendency to fail to make proper use of the very important knowledge already acquired of the disease and its treatment In the twenty minutes allotted for my paper I attempted to bring out what appears to me to be the important factors influencing the relative value of such medical and surgical treatment as is now available for the relief of patients afflicted with gastric and duodenal ulcer If the commonly accepted conception of peptic ulcer is correct, namely that hydrochloric acid and the associated digestive action of the gastric juice constitutes one of the greatest known hindrances to the healing of the clinical type of peptic ulcer that is amenable to medical or surgical control then it must follow that in the light of existing knowledge the maximum efficiency in the treatment of the unremoved ulcer cannot be attained without the use of alkalis in carefully regulated doses sufficient to neutralize the free hydrochloric acidity as employed in our clinical work

DR THOMAS R BROWN Baltimore I think that some persons perhaps misinterpreted some of the points of my paper The point I wish to make is that the fundamental principle of diet has been frequent feedings with nonirritating diet the principle which has been prevalent since Leube years ago reported his large series of cases in which he claimed

90 per cent of cures The obligation we owe to Dr Sippy is that he has reiterated the importance of frequent feedings The great advantage of Sippy's technic is its ease of application, it is fool-proof as diets go and that is a great advantage Dr Coffey said that results were obtained by Sippy that are not obtained elsewhere, that is true, but it is not due primarily to the diet but to the associated psychotherapy, the unconscious individualization I am perfectly sure that some patients do better on milk and cream than on cereals and that some do better on cereals than on milk and cream I am not convinced by this discussion as to justifiable optimism concerning the results When I think that more than twenty years ago exactly the same principle of treatment was insisted on by Leube and others in Germany when I realize that exactly the same percentage of cures was claimed by them, I do not see how we can honestly say we have made great progress We do not know the underlying causes, we do not know the fundamental factors A neuropathic may have hypersecretion all his life and never develop an ulcer One may have teeth so foul that they are simply breeding places of all kinds of streptococci, and yet have no ulcer Frankly, we do not know why an ulcer does develop How can any one be really optimistic when he remembers that Kocher, in reporting his great series of gastro-enterostomies said that practically every patient was cured, and at the same time Mathieu reported his hundreds of cases similarly headed with not one who had not some symptoms left behind? We have made progress but we honestly owe most of this to the surgeons, and, although I am not a surgeon, I believe the major knowledge has come from our surgical brethren from their correlation of preoperation signs and symptoms with operative findings I think that every clinician who has made real progress has done so by following up operative cases We have made progress in surgical technic tremendous progress, we have made progress along diagnostic lines, notably radiologic, and the realization of the value of periodicity of symptoms in ulcer, but why an ulcer should heal in the autumn and not break out until the spring we do not know One of the additional reasons for surgical treatment in these chronic conditions is that we as Americans do not take kindly to supervision We are hard to handle although a person of great personality may keep a patient on a regimen for years But after all, we are still waiting for some one probably not a medical man or a surgeon, but some man experienced in biochemistry and bacteriology, who will tell us why these ulcers develop Until then I feel that we shall make a great deal more progress by exhibiting humility for what we have not done rather than enthusiasm for what we have done

REPORT OF AN OUTBREAK OF BOTULISM

CHARLES G BEALL M D
FORT WAYNE, IND

March 11, 1922 at 1 p m, a meal was served, at the Lakeside Hospital at Kendallville, Ind, of canned salmon and canned spinach Within from twelve to twenty-four hours nine persons, all of whom had partaken of this meal, and all of whom had certainly partaken of the spinach, developed typical symptoms of botulinus poisoning, consisting of abdominal cramps, vomiting, diplopia, ptosis, dysphagia and aphonia All persons who ate some of the spinach developed symptoms No one in the hospital became ill who had not partaken of the spinach, and there were four or five, though they did eat the salmon Antibotulinus serum was requested by telegraph from Prof Robert Graham at the University of Illinois thirty hours after the spinach was eaten At the same time a similar telegraphic request was sent to Dr G W McCoy, director of the Hygienic Laboratory, Washington, D C The first doses were given within forty-nine hours of the time the spinach was eaten

REPORT OF CASES

CASE 1—Mrs W, aged 28 on whom colporrhaphy had been performed, March 8, and whose convalescence had been normal ate spinach, of unknown amount The symptoms were very similar to those in Case 2, but more severe At 6 a m and 1 p m, March 12, the patient had respiratory failure, and artificial respiration had to be started March 12, at 8 p m she was totally blind, and there were marked ptosis, dysphagia, complete aphonia, and mydriasis, the edges of the optic disks showed blurring and some hyperemia, she barely moved the jaw and the tongue could not be protruded She died, March 12, at 9 p m

CASE 2—Mrs H, aged 35, who had undergone colporrhaphy March 8 with normal convalescence, had eaten two teaspoonfuls of spinach March 12 at 1 a m, she began to complain of dizziness, nausea, vomiting and griping pains in the abdomen A few hours later she developed dysphagia, and twice had an almost fatal strangling spell when attempting to drink water She also had partial aphonia, burning in the epigastrium, and dryness of the throat Examination, at 8 p m, revealed masklike expression, marked ptosis mydriasis reaction of pupils slightly to the light, partial aphonia slight conjunctival injection, and cold body The condition became progressively worse Treatment consisted of castor oil and enemas and digitalin hypodermically March 13 at 2 p m 10 c c of Type A serum was administered hypodermically All symptoms progressed rapidly, and the patient died at 7 p m, March 13

CASE 3—Mrs B aged 62 a cook at Lakeside Hospital, had eaten two sauce dishes of spinach At 1 a m, March 12 she developed dizziness vomiting, griping pains in the abdomen marked ptosis of the eyelids amblyopia, diplopia, mydriasis aphonia dryness of the mouth, marked restlessness and orthopnea All these symptoms became progressively worse and the patient died, March 13, at 2 p m

CASE 4—Miss H aged 35, a nurse, had eaten a sauce dish of spinach Symptoms began at 5 p m March 12, with dizziness, transient amblyopia and diplopia, and abdominal cramps March 13 the condition became worse, with development of dysphagia, dryness of the throat speech difficulty and mydriasis Urinalysis revealed specific gravity, 1 027, no albumin and no sugar March 12, at 2 p m, 10 c c of serum Type A was given March 14 at 4 a m the patient swallowed water and talked better, 10 c c of serum was given March 14 at 9 30 a m, 10 c c of Type A serum was given and at 2 p m 10 c c In addition, she was given castor oil digitalin and morphin The symptoms became progressively worse, and the patient died at 3 30 p m, March 14

CASE 5—Miss B, aged 26, a nurse, had eaten a sauce dish of spinach March 12, at 5 p m, she developed dizziness nausea cramps in the abdomen, amblyopia diplopia, dysphagia mydriasis and partial aphonia Urinalysis revealed specific gravity 1 029, no albumin and no sugar Castor oil and enemas were given At 3 p m, March 13, 10 c c of Type A serum was given, and at 10 p m 15 c c The patient could no swallow, and was barely able to talk At 4 and at 9 30 a m, March 14 10 c c of Type A serum was given, and at 11 p m 40 c c of mixed Type A and B serum March 15 the symptoms began to improve The patient left the hospital March 28 still weak with slight symptoms of "limber" neck May 6, she reported that she still had occasional abdominal cramps, and, when tired, the neck muscles became very weak

CASE 6—Mr N, aged 50 a patient at Lakeside Hospital, with fractured hip had eaten a sauce dish full of spinach March 12 at 2 p m, he developed symptoms of nausea, vomiting, dizziness, cramps in the bowels, amblyopia, dysphagia, aphonia dryness of the mouth, and complete ptosis of the left eyelid Urinalysis revealed specific gravity, 1 030 no albumin, and no sugar Castor oil and enemas were given

March 13, at 2 p m, 10 cc of Type A serum was given, at 10 20 p m, 15 cc, at 4 a m, March 14, 10 cc, and at 9 30 a m, 10 cc At 11 p m, 40 cc of mixed Type A and Type B serum was given March 15, the patient was better He continued to improve, and was well at the end of a month

CASE 7—Miss S, aged 26, a nurse at Lakeside Hospital, had eaten a few bites of spinach March 12, at 5 p m, dizziness, nausea, vomiting, abdominal cramps, slight amblyopia transient diplopia, later dryness of the mouth, slight aphonia and mydriasis developed All these symptoms were more marked the next day Urinalysis revealed specific gravity, 1 028, no albumin, and no sugar March 13, at 2 p m, 10 cc of Type A serum was given, at 10 20 p m, 15 cc, March 14, at 4 a m, 10 cc, and at 9 a m, 10 cc At 11 p m, 40 cc of mixed Type A and Type B serum was given March 15, the symptoms were less severe, and from that date there was a gradual improvement in all the symptoms April 15, the patient still had slight transient amblyopia, slight dysphagia, and prickly sensations in the arms May 10, the throat still became quite dry, and the patient was rather weak

CASE 8—Miss F, aged 30, a nurse, had eaten four teaspoonfuls of spinach The symptoms began March 12, at 7 p m, with dizziness and nausea, later vomiting, no dysphagia, no aphonia and no diplopia She was given 10 cc of Type A serum, March 12, at 9 p m Symptoms of dizziness and cramps of the bowels continued for about two weeks At present the patient is perfectly normal

CASE 9—Dr G, aged 48, ate two teaspoonfuls of spinach, at 2 p m, March 12, and three hours later began to take castor oil, Epsom salt and enemas because of the symptoms of the other patients Urinalysis revealed specific gravity 1 028, no albumin, and no sugar March 12, at 8 p m, 10 cc of Type A serum was given Later, slight symptoms of amblyopia developed and the patient had cramps in the bowels for about ten days At present he feels normal, except that he has not quite the usual amount of ambition

The serum was given subcutaneously All the patients who lived developed varying degrees of urticaria from seven to ten days after the serum was given The Type A serum was furnished by Professor Graham, and the polyvalent serum Types A and B was furnished by Dr J C Geiger of the U S Public Health Service, who arrived in Kendallville, March 14, with a supply of serum prepared by the New York Board of Health

ANIMAL EXPERIMENTS

A guinea-pig, March 13, at 4 p m, was given, by mouth, about 1 dram (4 gm) of suspected spinach In the morning the pig seemed "dopy," and could not use the hind legs well There were violent twitchings and tremblings if forced to walk A peculiar "croakiness" of the voice was noted The animal grew rapidly weaker, and convulsive movements were more marked It died, 10 a m, March 14 Necropsy revealed engorgement of the blood vessels, congestion of the internal organs, especially the liver and kidneys, and marked congestion of the lungs The lower bowel was empty The upper bowel was distended with gas

A guinea-pig was injected intraperitoneally, March 14 at 10 a m, with 0 5 cc of saline extract of the suspected spinach Within an hour the guinea-pig had developed the peculiar "croakiness" of voice, but this was the only noticeable symptom up to 6 p m of that day The guinea-pig was found dead at 8 o'clock the next morning Necropsy revealed congestion of the liver, kidneys and lungs The lower bowel was empty The upper bowel was distended with gas

A guinea-pig injected at the same time with a small amount of saline extract of salmon developed no symptoms

A guinea-pig injected, March 15, with a mixture of 0 5 cc of saline extract of the spinach and 1 cc of Type A antibotulinus serum developed a slight "croakiness" of the voice and some diarrhea, but these symptoms were off in a few days, and the animal seemed as well as usual Necropsy, March 24, revealed no congestion of the internal organs, but there was engorgement of the blood vessels of the intestines and the abdominal wall There were numerous adhesions between the intestines, and a portion of the bowel was much distended with gas

A chicken fed 1 dram (4 gm) of the spinach, developed no symptoms

Dr Margaret Grant conducted these experiments

A specimen of the spinach and the salmon had been sent to Dr Graham, and on March 15 he reported the spinach to contain Type A botulinus toxin Dr Geiger also isolated *B botulinus* from the spinach, of which the minimal lethal dose for mice proved to be something between 0 0001 and 0 00001 c c

Two cans of spinach, the last of the hospital supply, had been opened two hours before using One of the cans looked perfectly normal, the other one showed a very slight amount of bulging at one end None of the partakers of the spinach noticed anything peculiar about the taste As soon as the disease was recognized, the supply houses in Kendallville readily agreed to hold all cans from this lot, and Mr Sweitzer of the Central District of the United States Department of Agriculture then traced and held all cans of this batch No more known cases have developed

Clinical Notes, Suggestions, and New Instruments

A CASE OF QUININ POISONING

CHARLES D LEACH, M D HUCHOW CHINA

Although cinchonism is of common occurrence, especially in malarial regions, I believe that severe cases of acute poisoning by quinin are not frequently reported Therefore this case may be of interest

A boy, aged 3 years and 4 months, found a box containing sugar-coated 2-grain quinin pills, April 15 1922 He ate a large number, probably not less than twenty or more than a hundred Finally he bit into one, and came to me for relief I gave him a dose of castor oil and made him vomit I did not see any pills in the vomitus, and concluded that probably he did not swallow any, after all That was about 1 p m In less than an hour he complained of severe pain in the general region of the umbilicus He had a normal bowel movement, after which he vomited until he had emptied his stomach of a hearty meal which he had eaten just before he swallowed the pills The vomitus contained partly dissolved pills

The patient was put to bed, but before his clothing could be removed he began to show signs of drowsiness and there was an irregular shaking of the head from side to side together with twitching of the muscles of the face I passed a stomach tube and washed out the stomach After this procedure he was somewhat cyanotic, but his pulse seemed to be in fair condition I then gave him a plain water enema followed by a soapstick to stimulate peristalsis and help in the elimination of the quinin The water returned nearly clear By that time he had passed into a semicomatose condition He continued to vomit at intervals of about fifteen minutes during the rest of the day The intervals gradually increased until midnight, after which time he vomited only once

About 4 o'clock in the afternoon I gave him a small dose of sodium bromid to combat the cinchonism The symptoms that I observed were vomiting, stupor twitching of the muscles around the mouth, combined with slow shaking of his head either from side to side or up and down occasional

spasmodic contraction of the flexor muscles of his limbs, flushed face, and dilated pupils Owing to the condition of stupor it was difficult to determine to what extent sight and hearing were affected, but he answered his mother when she spoke in a low tone about two hours after the symptoms began During the night, however, he did not respond when spoken to, or give any sign of either hearing or seeing Understanding that quinin has a tendency to depress reflex action, I tested him by scratching the sole of his foot Usually he is very sensitive to the least 'tickling" of his feet but this time I was not able to cause him to move his foot

As the vomiting ceased during the night, the patient rested more and more quietly, and the latter half of the night he slept very soundly He awoke soon after daylight and for the first hour seemed quite confused, but gradually became clearer until the mental condition seemed normal The sight and hearing also seemed normal, although he made a remark about thunder that made us think that his ears were roaring

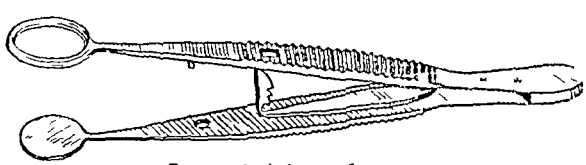
No rash developed after this overdose of quinin, although a year or more previously the patient developed a rash after a therapeutic dose of quinin

IMPROVED CHALAZION FORCEPS

SAMUEL W GREEN, M.D., BROOKLYN

The advantages of this revised instrument are many It enables the operator to complete a chalazion operation more speedily and safely, and with no resulting postoperative trauma to lids

The locking device is regulated with three notches to enable the operator to regulate the tension on different lids and also to hold the instrument on the lid especially if the



Improved chalazion forceps

operator wishes to pick up another instrument and an assistant is not present to hand it to him It saves the task of eversions of the lid so many times, as was experienced with the older instruments when they slipped from the lessening of tension by the operator's fingers It will also be noted that the ring is larger than the disk of the instrument This has been made so as to avoid the strangulation of the lid tissues which was too often a result from the older instruments because the operator may have handled his instrument a little too firmly to prevent it from slipping For the same reason the surface of the ring that approximates the disk has been flattened

All in all, this instrument has proved useful in my chalazion procedures, and may be heartily recommended

161 Clinton Street

Precocious Menstruation—In the first of the two cases reported by S Tronconi in the *Clinica Pediatrica* **3** 199, 1921 the recurring monthly genital hemorrhages in the girl of 6 were not influenced by tonics, arsenic, hot baths, ergot or other measures, but they did not return after a course of treatment with extract of mammary glands In the other child, an infant of 12 months, the genital hemorrhage was more continuous, and the final discovery of a tumor cleared up the case In the first case the hemorrhage returned the sixtieth day after the organotherapy had been suspended The hemorrhage ceased entirely only when enough of the mammary gland extract had been given to overcome the excessive functioning of the ovaries Eighteen months later the child seemed in good condition, but had not grown any taller, and the thyroid had increased in size The precocious development of breasts and growth of body hair had persisted unmodified

VACCINATION IN THE PHILIPPINES STILL EFFECTIVE

VICTOR G HEISER, M.D.
Consultant in Health to the Governor General of the Philippine Islands
AND
CHARLES N LEACH, M.D.
MANILA, P. I.

Recently many publications and statements have been circulated throughout the United States alleging that vaccination in the Philippines had not given protection against smallpox Quotations from annual reports of the Philippine Health Service have been cited by the antivaccinationists showing that more than 50,000 deaths from smallpox have occurred in the Philippines during the last few years The inference is that these deaths have occurred among the vaccinated The inference is entirely without foundation, as the direct opposite actually occurred The deaths are recorded almost entirely among the unvaccinated

It may be recalled that during the Spanish regime and for some years after the American occupation more than 40,000 deaths from smallpox occurred annually in the Philippines When systematic, properly controlled vaccination was instituted, the disease disappeared in the wake of the vaccinators A striking example of this fact is furnished by the mortality statistics for the provinces surrounding Manila The death rate from smallpox in these provinces was reduced from 6,000 annually to zero, after a thorough campaign of vaccination In the city of Manila there was not a death from smallpox for seven years prior to 1914 When the vaccination of the entire Philippine population was completed, so far as practicable, instead of 40,000 deaths a year there were only a few hundred, and these occurred in remote places among persons whom it was impossible to reach with potent lymph The temperature in the Philippine Islands ranges from 90 to 100 F nearly the entire year, with the exception of the mountain regions of Northern Luzon Vaccine under such conditions of temperature would remain potent only a few days after it left the ice As ice is not obtainable in many sections of the Philippines, it was not possible to supply effective lymph, hence many remained unprotected, and among these the disease was kept alive

After 1914, general vaccination of new-born children and other unprotected persons was not effectively carried out It is true that the records show that sufficient quantities of vaccine were made and sent out, but it is likewise true that the results of careful investigations instituted recently show that much of the vaccine was never applied, or not used until it had deteriorated Minor health officials and vaccinators found it much easier simply to report vaccinations than actually to carry out the procedure Quantities of vaccine virus were actually discovered in waste paper baskets In some instances many more vaccinations were reported than would have been possible with the quantity of vaccine sent to the vaccinators In another instance the total vaccinations reported in Pangasinan exceeded the population by 50,000 Thus, a huge unvaccinated population came into being, and it was only necessary for the ever present spark to fall among them to start the conflagration The spark fell, and in consequence more than 50,000 unfortunate victims have lost their

lives It is extremely regrettable that, through the circulation of half truths in the United States regarding vaccination in the Philippines, a strong effort is being made to influence legislatures to discourage vaccination against smallpox This can only result in the sacrifice of more lives When the situation in the Philippines was finally revealed, active vaccination was resumed, and the islands are again almost free of smallpox Fortunately in recent years methods have been discovered for making vaccine that will remain potent under tropical conditions Consequently, it is now possible to reach many persons who were inaccessible before

Percentage of cases among protected		14

Smallpox Deaths		
Among Successfully Vaccinated	Among Others	Total Deaths
90	899	989
Percentage of deaths among unprotected		93
Percentage of deaths among protected		7

Table 1, furnished by Dr Salvador V del Rosario, assistant director of health, shows the age incidence among those attacked in the typical province of Pangasinan It will be seen that more than 88 per cent occurred within the age groups that should have been vaccinated since 1914 The history in the other provinces is more or less the same Still more interesting, however, is the effect and incidence of smallpox among the vaccinated and the unvaccinated The Philippine Health Service furnished figures for the city of Manila for 1918, which is the year that the smallpox outbreak reached its greatest proportions (Table 2) Reducing Table 2 to simpler terms gives the result presented in Table 3

The completed records for the provinces are not yet available but those which have been examined show practically the same results as Manila and it would therefore be useless repetition to reproduce them

In brief, then the Philippines, since 1918 have had one of the greatest smallpox catastrophes of modern times Fifty thousand people perished On the basis of population, the islands lost ten times as many lives from smallpox during 1918-1920 as the United States lost from casualties in the World War

The death toll in the Philippines could have been avoided The figures conclusively show that 93 per cent of the deaths occurred among the unvaccinated

The 7 per cent that occurred among the successfully vaccinated would probably have been still further reduced if a virulent strain of smallpox had not developed among the unvaccinated and thus produced an infection which the ordinary immunity of the vaccinated was unable to neutralize

There are many side lights that confirm the efficacy of vaccination against smallpox in the Philippines The crews of interinsular vessels numbering many thousands were regularly vaccinated prior to 1914, and for ten years there was not a single death from smallpox among them After 1914 the vaccination of new seamen entering the service was not regularly carried out In 1918 no less than fifteen vessels had smallpox among their crews Vaccination in the middle of the outbreak of 1918 was vigorously resumed and no further cases occurred, although smallpox was very prevalent in Manila and at ports of call

The Chinese in the islands number more than 30,000 Owing to the strict registration which is maintained, it is comparatively easy to locate them and they are regularly vaccinated There was scarcely any smallpox among the Chinese, although it was raging all about them

SUMMARY

The recent outbreak of smallpox in the Philippines, in which more than 50,000 persons lost their lives, again confirmed the great value of vaccination as a protective agent against smallpox The overwhelming evidence made up of some seven million vaccinations performed prior to 1914, which resulted in bringing smallpox under complete control, has been further supplemented by the outbreak of 1918 In this later outbreak, 93 per cent of all deaths from smallpox occurred among those who were unprotected by vaccination

The deaths among the remaining 7 per cent were largely due to a virulent strain of infection which probably developed among the unvaccinated

The records further show that 89 per cent of the cases of smallpox occurred among unvaccinated children the majority of whom were born after 1913

When effective systematic vaccination was resumed in 1918, smallpox again disappeared in the wake of the vaccinators The disease showed no signs of abating anywhere until vaccination in the stricken areas was again carried out

CONCLUSIONS

1 Vaccination is the greatest safeguard against smallpox

2 In countries like the Philippines, tremendous catastrophes occur unless the entire population is thoroughly vaccinated against smallpox

3 Millions of vaccinations have been made in the Philippines without the loss of life or limb, or any observable effect on health

4 In the past, those who have advocated the abolition of vaccination have been the cause of many of the deaths among the unvaccinated In view of the frightful loss of life that may occur in smallpox epidemics they are assuming a grave responsibility indeed if they continue their campaign

FACTORS IN THE CAUSATION OF BOTULISM

No one who has followed the recurring reports of botulism outbreaks in this country can have failed to notice that certain articles of food are implicated much more frequently than others First come the foods preserved by heat Since the air is expelled in the heating process and since the containers of these foods must be hermetically sealed, it is easy to see that the anaerobic conditions so produced provide particularly favorable opportunities for the growth of any *Bacillus botulinus* spores that have survived the heating process As with other bacteria, so here, growth is hindered by a high concentration of sugar or brine or by a marked acid reaction Botulism from jam or candied fruits or from brine-pickled green olives is unknown, indeed, the disease has been very rarely attributed to the use of any sort of preserved fruit

Since botulism from canned foods is always traceable to imperfect sterilization, to failure to destroy the spores of *B botulinus,* it is not surprising that a relatively high proportion of botulism outbreaks should have been traced to foods canned in the household, where facilities for maintaining cooking temperatures considerably above the boiling point are not always readily available Commercially canned foods, however, are by no means exempt, and several instances are now on record in which foods canned on a large scale by modern processes have given rise to cases of botulism The Kendallville, Ind, outbreak, which is described in this issue,[1] is an example of poisoning due to a commercial product

While the reasons for the apparently greater liability of some foods to contain the botulinus toxin are quite obscure, and while the conditions under which botulinus toxin is produced are possibly connected with the composition of the foodstuff and still remain to be worked out, there are other instances in which a plausible explanation may be advanced It is evident that relative ease of heat penetration must be an important factor in attempts at heat sterilization Certain foods are much more easily dealt with in this respect than others Heat penetration is hardly a factor in canning soups, for example From this standpoint it is tempting to conclude that the recent outbreaks of botulism traced to eating canned spinach, such as the one at Kendallville, afford an illustration of the importance of securing adequate heat penetration Spinach and some other foods are recognized as presenting special difficulty There is no doubt that with such foods the size of the container and the amount of material in each can are important factors in the possible causation of botulism It is reassuring to find that the interests concerned, including state and national health authorities, are alive to the difficulty of the situation, and that suitable standards for the size of the can and amount of material as well as for sterilizing temperatures are being strictly applied

SUNLIGHT AND MEDICINE

Although light is an almost omnipresent factor in everyday life, its possible influence on biologic processes other than vision received very little scientific consideration until recent years The reactivity of the skin to light and the relation of this to pigmentation has been recognized and given some consideration in climatology The work of Finsen in his Light Institute at Copenhagen probably represents the first systematic effort to study the biologic effects of light and its possible therapeutic uses[1] Of late, the profound importance of this subject has been forcibly brought to public attention through the indisputable demonstration by several groups of investigators both here and abroad that sunlight and notably the ultraviolet rays have a marked curative effect on certain forms of rickets, as well as a prophylactic influence where this disease is liable to develop[2] The influence of photodynamic substances that may sensitize the organism to light has been noted from time to time in THE JOURNAL

In the effort to elucidate the possible chemical reactions associated with these various light effects, attention was focused first of all on the ultraviolet rays There is evidence on record that these may act on proteins so as to render them less soluble Solutions of albumin in quartz vessels behave like solutions of the more readily precipitated protein globulin after being subjected to ultraviolet rays Ordinary glass is a barrier to these potent rays, a fact which should always be borne in mind in contrasting the possible effects of sunshine indoors and outdoors The harmful effects of light on bacteria may depend on such changes in the protein constituents of their living protoplasm

Recently Young[3] has found in the Biochemical Laboratory at Cambridge University in England that proteins such as serum albumin and egg albumin which

2 Hess A F Newer Aspects of the Rickets Problem J A M A 78 1177 (April 22) 1922

3 Young E G The Coagulation of Protein by Sunlight Proc Roy Soc London (B) 93 235 (March 1) 1922

have been sufficiently purified by repeated crystallization become sensitive to intense light, either sunlight or strong arc illumination, from which the infra-red and ultraviolet rays have been removed The proteins may become denatured and precipitate The reaction and presence of electrolytes play a part in facilitating these unique responses to light It is too early to discuss the theories of these manifestations of radiant energy, but if the preeminent constituents of living cells can be so readily disarranged chemically by light, scientific medicine must become alert to consider what the newer knowledge may ultimately have in store for our profession

ANTHRAX IN AMERICAN TANNERIES

Anthrax in man is a disease of such serious moment that its menace scarcely needs to be emphasized The fact that it is largely confined to persons engaged in certain occupations which favor infection with *Bacillus anthracis* has perhaps tended to obscure the incidence and seriousness of the malady The more recent outbreaks of cases attributable to infection from shaving brushes have tended to arouse a greater interest in the subject and to awaken public health officials in many places from the apparent lethargy in regard to it The United States still lags behind the European countries in preventive legislation relating to anthrax, and in enforcement of active measures to stamp out the disease as well as to protect those most likely to contract it Anthrax in man is most frequently encountered among workers on hides, hair, bristles, wool, etc, and in laboratory workers, veterinarians, meat inspectors, farmers, cattlemen and butchers So-called pulmonary anthrax, which describes the cases arising from inhalation of dust from infected materials, may show a mortality of 50 per cent The type of disease represented by "malignant pustule" is particularly severe Such facts should serve, therefore, to support every effort which industrial hygiene may initiate in the direction of reform

Recently compiled statistics from a representative state may help to give emphasis to what has already been noted In Pennsylvania, according to the investigations of Smyth and Bricker,[1] slightly more than 8 per cent of the 7,458 men engaged in fifty-seven cattle hide tanneries were directly exposed to anthrax risk during the period under consideration In nineteen goat skin tanneries employing nearly 6,000 men, somewhat more than 7 per cent were directly exposed Thus, a total exceeding 1,000 men, or not quite 8 per cent of the employees, was exposed to the serious danger Of these, at least 119 contracted anthrax in the course of the twelve years included in the Pennsylvania study, and four more cases developed in those handling raw hides or skins, making 123 cases in all, or more than 11 per cent of the number of directly exposed tanners Seventy-three of these cases were due to the handling of cattle hides, and fifty to the handling of goat skins One fifth of the patients died

This is not the place to discuss the comparative danger of hides from different sources The fact that during a five-year period a yearly morbidity rate of almost 2 per cent from anthrax among directly exposed tannery employees is on record suffices to point to the lesson Hides and skins imported into this country are supposed to come in under quarantine unless accompanied by a consular certificate stating that they are from a district free from anthrax But the experience of Smyth and Bricker[1] agrees with that of others to the effect that this certification is worse than useless, since it merely establishes a false sense of security among the tanners and freight handlers It is stated that anthrax has been contracted from the handling of both dry and wet salted hides and skins, and from both certified and uncertified stock, and anthrax bacilli have been isolated from both It is high time to give more serious consideration to the anthrax problem The tanneries must no longer be allowed to receive anthrax-infested raw stock

Incidentally, it should be noted that treatment in hospitals has generally been more favorable than the less rigorous therapy of unhospitalized patients The use of antianthrax serum with excision of the local lesion has given good results The Pennsylvania experts particularly recommend the injection of phenol (carbolic acid) solutions of from 25 to 50 per cent strength locally around the area of the initial lesion Early diagnosis, prompt hospitalization if possible, and absolute rest, they conclude, are essential for success in any form of treatment

WATER DRINKING AND HYPERTENSION

Fewer features of clinical medicine are the subject of more vigorous debate and of almost acrimonious discussion than is arterial hypertension With respect to its causes and its therapeutic management, as well as the prognosis of individual cases, the widest ranges of opinion have been expressed Through the development of sphygmomanometry, the rapid, fairly accurate estimation of blood pressure has been made possible for any practitioner Consequently, on the one hand it has been remarked of the simple and most important test for high blood pressure that "any social worker would be the better for knowing it and could learn it in fifteen minutes',[1] whereas, on the other hand, physicians are warned against the fancy that the management of hypertension consists in watching a column of mercury, or that success is measured in millimeters[2]

1 Smyth, H F, and Bricker Elizabeth Analysis of One Hundred and Twenty Three Cases of Anthrax in the Pennsylvania Leather Industry J Indust. Hyg 4 53 (June) 1922

1 Cabot R C A Layman s Handbook of Medicine, Boston Houghton Mifflin Company 1916 p 172
2 Osborne O T and Tibbein Morris Handbook of Therapy Chicago American Medical Association 1920 p 368

This is not the place in which to debate whether permanent pathologic alterations in the blood vessels, nervous reflexes, or poisonous products producing vasoconstriction are the prime factors in the genesis of hypertension, or whether the blood pressure manifestations of acute nephritis, eclampsia or uremia are in any degree due to anatomic changes in the heart or blood vessels It is obviously not without serious moment for the management of the individual case to know the precise pathology and even the ultimate etiology of the condition under observation In the present stage of our knowledge, however, facts are more valuable than hypotheses

Certain striking facts regarding blood pressure have recently been recorded at Aberdeen, where Orr and Innes [3] have observed the influence of increased water ingestion on the blood pressure of some apparently normal subjects and also in pathologic cases in which there was high arterial tension The addition of from 2 to 3 liters (quarts) of water to the normal daily consumption is followed by a distinct fall in both systolic and diastolic pressure The fall is not accompanied by an increase of either the rate or the force of the heart beat, and the decreased pressure is maintained for some time after the extra water has been excreted Clinicians have generally warned against large fluid intakes when the kidneys are incapable of reacting properly, and the therapeutic value of restrictions has been urged by Allen [4] in THE JOURNAL

The British investigators also point out that when diuresis is unable to keep pace with the intake of water, especially in cases of high arterial tension, the fall in pressure is sometimes preceded by a rise beyond the original level, which persists until the bulk of the extra fluid has been eliminated The renal conditions must never be overlooked

However, it is the cases of fall of pressure attendant on water drinking, as well as the reported alleviation of disagreeable subjective symptoms in some of the patients with hypertension studied, that challenge attention The diuretic properties of water taken by mouth are generally recognized Orr and Innes incline to the view that the chief factor in producing the fall of pressure is the elimination of pressor substances that cause arterial constriction and thereby produce an unnecessarily augmented arterial tension Friedrich Muller of Munich long ago expressed the conviction that the same toxic substances which produce uremia may, in lessened concentration, affect the vasomotor center, thus causing a heightened blood pressure By others the seat of origin of the hypothetic toxins or substances with pressor effects has been assigned now to the alimentary tract, now to the tissues themselves The fact that chemical substances like the amins which exert a vasoconstrictor effect in very small doses have been isolated on various occasions has helped to render the theories of a toxemic etiology for certain cases of hypertension more appealing If it shall prove to be true that diuresis induced by water drinking in patients with adequately functioning kidneys serves in reality to "flush out" pressor substances from the system, the discovery will be an important one The present gaps in our knowledge, however, remain conspicuous

Current Comment

HYDROGEN SULPHID AS AN OCCUPATIONAL POISON

The possible menace of hydrogen sulphid as a cause of occupational disease has lately been brought into a greater prominence than it has heretofore attained Most physicians think of this foul smelling gas primarily as an artificial laboratory product bearing little if any relation to the work of the everyday world Its toxicity, to a large extent, has been minimized because the objectionable odor associated with sulphureted hydrogen acts as a protective warning to prevent those who become exposed to the gas from inhaling any considerable quantity In certain mines it has become somewhat familiar under the name of "stink-damp," and is found occasionally as an occluded gas in coal seams or places where there is a decomposition of pyrites in the presence of moisture [1] Klein [2] has lately directed attention to the role of hydrogen sulphid as a dangerous component of the gases collecting in sewers, cesspools and similar places in which dejecta are permitted to putrefy without ventilation In the absence of a liberal supply of oxygen, protein material generates, *through the action of anaerobic putrefactive micro-organisms*, a mixture of gaseous products including nitrogen, carbon dioxid, methane, ammonia, hydrogen and hydrogen sulphid The proportions of these components may vary, depending on the bacterial pabulum from which they arise Klein has emphasized the fact, however, that the really toxic menace to persons exposed to such products lies in the hydrogen sulphid, which may attain a concentration as high as 8 per cent by volume Under such conditions there is great danger because of the high toxicity of the gas Usually the danger is minimized because of the low concentrations of hydrogen sulphid concerned Out of twenty-nine cases of poisoning with this product reported by the chief inspector of factories and workshops in England for the years 1908 to 1912, only five were fatal [3] Yet, according to Haggard [4] of Yale University, inhalation of hydrogen sulphid kills in a concentration of 7 parts per 10,000 after the lapse of some time Larger concentrations are followed by more prompt fatalities According to Haggard, and contrary to conventional beliefs, hydrogen sulphid, when inhaled,

does not form a compound with the respiratory pigment of the blood, hemoglobin, nor does it combine with the sodium of the blood It is transported dissolved as a gas, which the blood has the property of oxidizing to less harmful products if the quantities involved are not so large as to threaten the function of vital organs before the gas can thus be detoxified

THE OCCURRENCE OF EXOPHTHALMIC GOITER

The possibility that despite the fact of their unlike physiologic symptoms some etiologic relationship may exist between endemic goiter and the type of hyperthyroidism known as exophthalmic goiter has more than once been referred to in recent years The incidence of endemic goiter and its geographic distribution are now fairly well known Its greater occurrence inland and away from the seaboard, both in this country and in continental Europe, is recognized, hence the designation of goiter regions has been applied to localities where this thyroid disorder abounds Exophthalmic goiter, if this somewhat inadequate nomenclature may be permitted for the purpose of description, is no longer such a rarity as it was assumed to be a decade or two ago Dependable statistics as to its geographic distribution might help to furnish an answer to the possible relationship of this disease to the other abnormal thyroid conditions Dock [1] has reported that endemic goiter districts are relatively free from exophthalmic goiter, but alleges that this is not true of Switzerland and France, or of the region of the Great Lakes of North America Dock also records the belief that the incidence of exophthalmic goiter is higher in England and on sea coasts than in some continental localities, but is very high in the interior of North America Statistics have just become available from the Medical Investigation Department of Guy's Hospital in London, where Campbell [2] has studied a group of more than a hundred cases, along with statistics from outside places These show that in England exophthalmic goiter is more common in the country than in the towns, more common in the West than in the East, and more common on the sea coast than inland It does not appear, to Campbell, to be specially prevalent in areas in which goiter is endemic This tentative conclusion may not be without significance in future discussions on both of the diseases

THE NATURE OF INSENSIBLE PERSPIRATION IN HEAT REGULATION

Every person continually experiences a loss of water from the skin in quantities that may become not inconsiderable under certain circumstances The cutaneous excretion of water is determined mainly by the need for regulating the temperature of the body, so that the amount leaving by way of the skin depends on the heat production of the body or on the external temperature, and is very little affected by the quantity of fluid consumed Under ordinary conditions, in which no visible collection of fluid on the skin surfaces occurs, the water lost is included in the so-called insensible perspiration According to observations on anomalous persons without sweat glands, the evaporation of water from the nonsweating skin may amount to 800 gm (28 ounces) a day In normal persons it will be noticed that the quantity of water thus given off increases with a rise of environmental temperature slowly up to a certain degree, and then rises rapidly This sudden increase occurs simultaneously with the activity of the sweat glands, resulting in the formation of visible sweat The insensible perspiration is therefore conventionally regarded as represented by evaporation of water from the surface of the cuticle itself apart altogether from the sweat glands If the removal of heat through the loss of water by insensible perspiration is a purely physical process, as it is commonly assumed to be, the transfer should be affected not only by temperature factors but also, to some extent at least, by the humidity of the surrounding air If the skin is to be regarded, so far as the insensible perspiration is concerned, merely as a membrane through which water is diffused into air obviously the process should be retarded when the external medium tends to be more saturated with moisture Several investigators have found, however, that in fact this is not necessarily the case Most recently, for example, in Schwenkenbecher's clinic at Marburg, Moog [1] has observed that at a fairly constant temperature of 25 C (77 F) increases of from 30 to 40 per cent in the relative humidity may actually be attended by increased invisible perspiration through the skin If such data are accurate, one cannot escape the conviction that this loss, instead of being merely a purely physical process dependent on the composition and temperature of the air, is a physiologic one varied by the necessities of heat regulation in the body Perhaps we may think of it, with Schwenkenbecher, as an insensible secretion of sweat rather than mere diffusion of water through the skin membrane

HARMFUL AMINS

Most students of the problem of intestinal obstruction—and there have been many—have come to the conclusion that one or more potent substances arise within the bowel under such conditions and are responsible for the characteristic toxic symptoms Whether the poisons are of bacterial origin or owe their genesis to aseptic changes in the mucosa and alimentary secretions remains debatable Whipple and his collaborators have been inclined to identify the toxins as proteose in character but their conclusions have been challenged Recently, however, evidence secured from several independent sources suggests that histamin, the amin derived from the amino-acid histidin, which in turn is a familiar cleavage product of proteins, is one, at least, of the possible chemical offenders Histamin, like other amins may arise through putrefactive changes in protein-containing materials It is among the more

potent of the bases to which bacteria thus give rise Micro-organisms capable of producing the amin have actually been isolated from the intestinal contents Lately, Meakins and Harington [1] in England have found histamin in obstructed colons in man, and now Gerard [2] of Chicago reports the occurrence of the same depressor base in experimentally produced contents of obstructed intestinal loops It would be unjustifiable to charge histamin or any of its companion products [3] with actual complicity in many of the ills of life referable to the bowel, yet the repeated finding of such potent products there points to the possibility that they may at times actually exert untoward effects Bronchial asthma has been described as an aminosis or amin intoxication, and urticarial reactions have also been associated with histamin [4] These amins deserve serious attention as possible pathogenic factors

Medical News

(PHYSICIANS WILL CONFER A FAVOR BY SENDING FOR THIS DEPARTMENT ITEMS OF NEWS OF MORE OR LESS GENERAL INTEREST SUCH AS RELATE TO SOCIETY ACTIVITIES NEW HOSPITALS EDUCATION PUBLIC HEALTH ETC)

ARIZONA

State Medical Meeting—At the annual meeting of the Arizona State Medical Association, in Prescott, June 14-16, under the presidency of Dr A L Gustetter, Nogales, the following officers were elected for the ensuing year president, Dr Harry T Southworth, Prescott vice presidents, Drs Charles A Thomas, Tucson, Roderick D Kennedy, Globe, and Arthur C Carlson, Jerome, treasurer, Dr Alvin T Kirmse (reelected), Globe and secretary, Dr Delamere Harbridge (reelected), Phoenix A motion by the president to secure the privilege of prescribing alcoholics was promptly tabled Resolutions were adopted to oppose the Sheppard-Towner bill and all "state medicine," and plans were made for a women's auxiliary to the state association

CALIFORNIA

Japanese Physician Sentenced—It is reported that S Wahaume, a Japanese physician was sentenced to five months in prison for practicing medicine without a license Wahaume was arrested in Sacramento several months ago on a nonlicense charge and forfeited a $500 bail when he failed to appear for trial

Hospital News—The Bard Memorial Hospital Ventura, will in future be known as the Big Sisters' Hospital——Dr James A Ramsay has assumed control of Hillcrest Sanatorium, Hemet, relieving Dr Verdo B Gregory, who formerly had charge of the institution——The present University of California Student Hospital, San Francisco, has been declared inadequate, and plans are under way to construct a new hospital of 100 beds, to be used by the faculty and students of the university Dr Robert T Legge is director of this hospital——Dr Alfred C Reed has resigned as director of the Ross Sanatorium

COLORADO

University of Colorado — The Denver city council announced, May 26, that an appropriation of $20 000 will be made as the city's contribution to the proposed University of Colorado Medical School and state hospital, which will be constructed in Denver This completes the $200,000 which it was necessary to obtain through popular subscriptions in order to take advantage of sums donated by the Rockefeller Foundation, the Carnegie Foundation and the Colorado state legislature, aggregating more than $1,500,000

CONNECTICUT

Yale University—At the commencement exercises of the university, President Angell announced that additions to the university funds for 1921 amounted to more than $5,500,000 The principal gift was the Harkness Fund of $3,000,000 Gifts and pledges made during the year for additional endowment of the school of medicine, toward the total of $2,000,000 needed to secure the contingent pledge of $1,000,000 from the general education board, total $390,000 This amount includes a pledge, received June 21, of an anonymous gift of $100,000, to be added to the principal of the Anna M R Lauder Foundation in the school of medicine, the income of which is to be used each year for the purposes outlined in the letter covering the original gift of this fund for the establishment of the department of public health In view of the continued progress made by the school of medicine, and of the gifts evidencing the interest of Yale's friends in its development, the general education board has extended the time for fulfilling the conditions of their appropriation from June 30, 1922, to June 30, 1924

DISTRICT OF COLUMBIA

Legislation Proposed for Tuberculosis Hospital—A bill introduced into the lower house of Congress by Representative Sproul provides for the erection of a hospital for the care of tuberculous pupils of the District of Columbia The sum of $150,000 is appropriated to carry out the proposed construction

GEORGIA

University of Georgia—Five additional professors for the medical department of the university were recently announced as follows Dr Eliot R Clark from the University of Missouri, professor of anatomy, Dr Richard V Lamar, professor of pathology, Dr Virgil P Sydenstricker, Augusta, professor of medicine, Dr Ralph H Chaney, Rochester, Minn, professor of surgery, and Dr Harry B Neagle, Adrian, Mich, professor of preventive medicine and hygiene All the present faculty were reelected——It was announced by the university faculty at the annual commencement exercises that the medical department of the university has been given $40 000 a year by the Rockefeller Foundation, the Carnegie Foundation, and the city of Augusta, through popular subscription, for placing the departments of medicine and surgery on a pay basis, and for general expenditures

ILLINOIS

Honor for Dr Humiston—At the eighty-fifth annual commencement exercises of Marietta College Marietta, Ohio, Dr Charles E Humiston of Chicago received the honorary degree of doctor of science, in "recognition of his efforts to raise the standard of the medical profession in all parts of the country"

New Appointments—Dr Charles Lieber has been appointed county physician of Lake County to succeed Dr Albert E Brown, who resigned recently——Dr Samuel F Paul was renamed for Rock Island and South Rock townships——Dr J M Wood has been appointed city physician of Moline——Dr John H Fowler was recently named for East Moline and Hampton

Chicago

Rush Medical College Alumni Elect Officers—At the annual meeting of the Alumni Association of Rush Medical College, held in Chicago recently, the following officers were elected president, E L Kenyon, vice presidents, F B Moorehead D C Wherritt and T C Galloway, treasurer, C O Rinder, secretary, C A Parker, necrologist J F Waugh, and directors for three years, H G Wells and G H Coleman

Donations to University—By the will of Seymour Coman of Chicago, University of Chicago is made trustee of his residuary estate, estimated to be approximately $145 000, the net income to be used for scientific research, with special reference to preventive medicine and the cause prevention and cure of diseases This bequest to be known as the Seymour Coman Research Fund——By the will of Alexander D Thomson of Duluth, Minn, the sum of $50,000 is

1 Meakins J and Harington C R J Pharmacol & Exper Therap **18** 455 (Jan) 1922
2 Gerard R W Chemical Studies on Intestinal Intoxication I The Presence and Significance of Histamine in an Obstructed Bowel J Biol Chem **52** 111 (May) 1922
3 Barger, G The Simpler Natural Bases London, Longmans Green & Co 1914
4 Sollman Torald and Pilcher J D J Pharmacol & Exper Therap **9** 391 (April) 1917

bequeathed to the university for use in the medical department to be expended under the direction of Dr Wilbur E Post and Dr Herman L Kretschmer, both of Chicago

IOWA

Personal—Dr Walter L Bierring, Des Moines sailed for Scotland, June 27, to attend the ceremony of his election as an honorary member of the Royal College of Physicians Edinburgh——Dr Jefferson B Blything has been reappointed city physician of Davenport——Dr Henry Albert, head of the department of bacteriology at the University of Iowa, Iowa City, has resigned on account of his health and will become head of the state board of health laboratories of Nevada——Dr James W Osborn was recently elected president of the Des Moines health center

KENTUCKY

Personal—Dr John M Williams has been elected president of the recently organized health board at Paris Dr Arthur H Keller was reelected city health officer of Paris and secretary of the board of health——Dr Joseph E Wells Cynthiana, and Dr James C Mitchell, Louisville, have been appointed members of the state board of health

LOUISIANA

New Physicians' Building—An eight story structure will be erected opposite the Touro Infirmary in New Orleans exclusively for physicians The cost of the building will be approximately $400 000 At the end of ten years physicians occupying offices in the building, will become permanent owners of the structure

Illegal Practitioner Charged—It is reported from Alexandria that the 'Rev Dr' J S Wright a negro who stated that he was a "doctor of divinity and a healer by faith" was tried and convicted, June 17, by Judge Hundley for practicing medicine without a license He was remanded for sentence Wright had been operating in the city for several weeks in a tent Dr Oscar Dowling president of the state board of health called on Wright and was advised that he was suffering from high blood pressure Wright gave him a prescription with directions for using, for the sum of one dollar

MARYLAND

Personal—Dr Randolph Winslow who for forty-nine years was associated with the school of medicine University of Maryland and with the University Hospital has left Baltimore on an extended automobile tour of the Southwest He will sail on a voyage to South America on his return In addition to severing his connection with the university, Dr Winslow has practically retired from active practice of his profession of surgery——Dr John M T Finney has left for Winnipeg Canada where he read the surgical address before the Canadian Medical Association which is in session——Dr Edward N Brush of Baltimore has returned from Quebec Canada where he attended the sessions of the American Psychiatric Association

MASSACHUSETTS

New England Roentgen Ray Society—At the annual meeting of the society held in Boston, June 2 the following officers were elected for the ensuing year president, Dr Arial W George Boston vice president Dr Ernest L Davis Springfield, and secretary-treasurer, Dr Adelbert S Merrill Boston

Massachusetts Medical Society—At the annual meeting of the society in Boston, June 13-14, Dr John Bartol, Boston was elected president, Dr Charles E Mongan, Somerville vice president, Dr Walter L Burrage Jamaica Plain secretary Dr Arthur K Stone Framingham Center treasurer and Dr Edwin H Bingham, Brookline librarian All officers were reelected with the exception of the vice president.

Harvard University Commencement—At the two hundred and eighty-sixth commencement of Harvard University thirteen honorary degrees and 1 401 regular degrees were conferred Dr Walter Belknap James, New York received the honorary degree of doctor of laws Gifts of $4 926 000 to the university were announced by President Lowell This amount included $100 000 from the class of 1897 in commemoration of its twenty-fifth anniversary

MICHIGAN

Honorary Degree for Dr Warnshuis—At the fifty-seventh annual commencement of Hope College Holland Dr Frederick C Warrshuis, Speaker of the House of Delegates of the American Medical Association, received the honorary degree of Doctor of Science for work in surgery, public health conservation and medical organization

Mentality of Prisoners Tested—Under the direction of Prof Guy M Whipple University of Michigan, tests for inmates of the state reformatory at Ionia designed to show what part mentality plays in crime were started, May 26 Dr R M Olin, state health commissioner, Dr McGregor and Dr R H Haskell superintendent of the Ionia State Hospital for the Criminal Insane assisted Professor Whipple The examination was authorized by the administrative board with a view to applying corrective measures where possible and also to furnishing the prisoners employment conforming to their mental development

MISSOURI

Decision Regarding Impounded Dogs—Mayor Kiel of St Louis has announced that he will remove the Humane Society from control of the dog pound because the Humane Society declines to deliver impounded dogs to the medical schools for scientific purposes as authorized by an ordinance passed by the board of aldermen recently The Humane Society has been instrumental in having a suit filed against the city to restrain the city officers from selling the dogs to medical schools on the ground that the ordinance is unconstitutional

Osteopaths and Physicians—The Springfield court of appeals has affirmed the finding of the lower court that an osteopath is not a physician or surgeon within the meaning of the law governing the practice of medicine and surgery The court of appeals quoted an opinion of the supreme court of Missouri as follows

> Osteopaths are not physicians or surgeons in any of the departments of medicine or surgery but may cure or relieve any disease of the human body according to the system method or science as taught by the American School of Osteopathy at Kirksville or any other legally chartered and regularly conducted school of osteopathy

NEW JERSEY

New Jersey Pediatric Society—At the annual meeting of the society held in Spring Lake June 21 the following officers were elected president Dr Eugene W Murray, Newark vice president Dr Frank W Pinneo Newark treasurer Dr Ernest G Hummel, Camden, and secretary, Dr Miller R Whitenack Newark

New Eugenics Bill—The house of assembly recently passed the new eugenics bill of the Rev Warren P Coon The purpose of this bill is to make uniform throughout the eastern part of the United States the repression of vice as advocated by the federal authorities, as a result of their experiences in the late war This act has already been adopted in twelve other states and punishes the male (especially when soliciting) as well as the female It enables the county court to put convicted women or girls on probation or send them to proper schools and it also takes care of taxicab assignations, which are not covered by the present law

NEW YORK

Hygiene Essay Contest—In order to stimulate interest on the part of high school students in problems of disease and hygiene Dr Nicholas Lukin offered a gold and silver medal to the two pupils of the Morris High School who would write the best essays on The Role of Bacteria in Disease Forty essays were submitted and it is believed that the contest served to stimulate greatly the interest of the students in these questions

Health Officers and Nurses Meet—The annual conference of the sanitary officers and public health nurses of New York was held in Saratoga Springs June 27-29 under the auspices of the state department of health Dr Hermann M Biggs state health commissioner opened the conference and introduced Gov Nathan L Miller Dr Victor C Vaughan Dr Livingston Farrand president of Cornell University and Dr George E Vincent president of the Rockefeller Foundation were among the speakers At a special session June 27 a demonstration of the wireless telephone and its uses in educating the public in health matters was given by the General Electric Company

Personal—Dr John Lorenzo Heffron has resigned as dean of the Syracuse University School of Medicine Syracuse effective June 15 This resignation terminates the connection which Dr Heffron has held with the teaching staff of the medical school for forty years during fifteen of which he has served as dean Dr Heffron was made dean emeritus

Dr Herman G Weiskotten, county necrotomist and professor of pathology in the college of medicine, was elected acting dean until October——Dr Francis S Mathews, New York, received the degree of doctor of laws, June 7, from Washington and Jefferson College at its one hundred and twenty-first annual commencement——Dr Harold L Amoss, associate member of the Rockefeller Institute for Medical Research, New York, received the degree of doctor of laws from George Washington University, Washington, D C, June 7 June 12, the scientific staff of the Rockefeller Institute gave a dinner in honor of Dr Amoss, who has been appointed associate professor of medicine at Johns Hopkins University, Baltimore——Dr Walter W Palmer, New York, received the honorary degree of doctor of science from Amherst College at commencement, June 21——Dr Moses Allen Starr and Dr Frederick Bierhoff recently sailed for Europe

New York City

Dinner in Honor of Dr Sobel—A testimonial dinner attended by more than 100 physicians and surgeons of this city was given, June 21, to Dr Jacob Sobel, assistant director of the bureau of child hygiene of the department of health, on the eve of his retirement after being in the service of the city twenty-three years Dr Sobel will go to Europe to study diseases of children with Professor Pirquet

Columbia University Establishes Public Health School—Under a bequest of the late Joseph R DeLamar, an institute of public health has been established at Columbia University The fund turned over to the university for the benefit of the school of medicine by the executors of the DeLamar estate amounts to $777 772 45 The new institute of public health will be primarily for research and the training of research workers, but it will afford instruction to students of medicine and others, and, as Mr Lamar's will provides, it will engage in giving wide publicity in popular form to the results of scientific investigation Dr Haven Emerson has been appointed professor of public health and administration

NORTH DAKOTA

State Health Survey—At the request of the state health officer, Dr Harley E French, the U S Public Health Service has assigned an officer to the state of North Dakota for the purpose of assisting in the organization of an adequate state health department Surgeon Robert Olesen, who has just completed a three-years service with the Wisconsin State Board of Health, has been detailed for this purpose A survey of the state's health needs has been completed and a plan submitted for an organization, based on the local requirements

OHIO

College of Homeopathy to Be Amalgamated—At a meeting of the board of trustees of the University of Ohio, June 19 the majority report of the committee appointed to make an investigation of the situation regarding medical education in the university was adopted This report provides (*a*) that the College of Homeopathic Medicine be discontinued on and after July 1, 1922, (*b*) that all buildings, instruments, appliances and material supplies of all kinds, now the property of the university and occupied or used by said college, be transferred to the jurisdiction of the College of Medicine, (*c*) that all students at present enrolled in the College of Homeopathic Medicine shall, on their individually expressed desire, be registered as students in the College of Medicine, with the grade now held by them in the College of Homeopathic Medicine and (*d*) that there be established two additional chairs, elective, in the College of Medicine, one to be known as the chair of homeopathic materia medica and the other as the chair of homeopathic practice, the date of such establishment to be from July 1

PENNSYLVANIA

Hospital News—Excavation has been started for a four-story building for the Cottage State Hospital Philipsburg——The newly erected addition to the Mount Sinai Hospital, Philadelphia, was dedicated, June 25 Judge John M Patterson made the dedicatory address

Dr Frazier Receives Chair of Surgery—Dr Charles H Frazier, formerly professor of clinical surgery in the University of Pennsylvania, has been made John Rhey Barton professor of surgery in that institution The appointment was made at the June meeting of the board of trustees Dr Frazier succeeds Dr John B Deaver, who will resign at the end of the present college year

WASHINGTON

Personal—Dr Rowe France has been appointed city physician of Seattle to succeed Dr Hiram M Reed——A farewell dinner was given, May 31, to Dr William N Keller, retiring superintendent of the Western State Hospital for the Insane, Fort Steilacoom Dr Keller was presented with a gold watch and Mrs Keller with a pearl necklace Dr David Livingstone will succeed Dr Keller——Dr A E Baldwin, Kettle Falls was recently elected president of the Stevens County Medical Society at Colville

CANADA

Canadian Medical Association—At the annual meeting of the association at Winnipeg, Man, June 20-23, the following officers were elected for the ensuing year president, Dr David H Arnott, London, Ont, vice president, Dr Walter L Muir, Halifax, N S, and secretary, Dr John W Scane, Montreal, Que The association proposes to investigate the feasibility of establishing a college of surgeons in Canada A committee was appointed to report on the matter at the next annual session Dr Edward W Montgomery, Winnipeg, is the retiring president

University News—At the Canadian Universities' Conference held in Winnipeg, recently, Dean Frank D Adams of McGill University, and Dean R W Brock of the University of British Columbia, urged on the delegates the necessity of founding a Canadian graduate school Dean Adams suggested that the graduate courses in Canada be pooled as they are in Germany, so that each student could avail himself of them without restriction——In a recent bulletin published by the Carnegie Foundation for Advanced Teaching, the union of six small universities in the provinces of New Brunswick and Nova Scotia is urged, making one large university at Halifax N S It is proposed to raise $4,500 000 for this purpose The institutions concerned are King's College Windsor, N S, Dalhousie University, Halifax, Acadia University, Wolfville, N S, Mount Allison University, Sackville, N B, St Francis Xavier's University, Antigonish, N S, and the University of New Brunswick Fredericton, N B——Included in the honors which have recently come to the graduates of McMaster University, Toronto, is the award of a valuable prize to Miss Marion E Stillwell, in the nurses' training course at the Toronto General Hospital J E Bates who graduated this year from the University of Toronto, won the Ellen Mickle Fellowship worth $1,200, for research work in pathology, under Dr W L Robinson

PHILIPPINE ISLANDS

University of St Thomas—The sum of 5,000,000 pesos ($2,500,000) has been appropriated by the Dominican Order which controls the University of St Thomas College of Medicine Manila, for the erection of a new concrete building, in which will be housed all the colleges of the university, the laboratories, the dispensary, the libraries, the hall, the chapel and its offices, leaving the old building which the university now occupies in the Walled City The site for this new building will be on the outskirts of Manila Construction work will be started in a few months A university hospital for the practice of the students of the college of medicine will be erected on the same site Dr Jose Luis de Castro is dean of the university

GENERAL

American Therapeutic Society—At the annual meeting of the association, held recently, the following officers were elected for the ensuing year president, Dr Charles G Jennings, Detroit, vice presidents, Drs Hermon C Gordinier, Troy, N Y, Arthur Parker Hitchens Washington, D C and C E Cooper-Cole, Toronto, Canada, secretary Dr Lewis H Taylor, Washington, D C, and treasurer, Dr Spencer L Dawes, New York

Prohibiting Importation of Horsehair Brushes—The House of Representatives this week passed the Winslow bill, prohibiting the importation and the shipment in interstate commerce of shaving and lather brushes containing horsehair In the Senate it was referred to the Committee on Interstate Commerce The purpose of the measure is to prevent the spread of anthrax, it having been discovered during the war by the U S Public Health Service and other health authorities that the disease was traceable to horsehair shaving brushes

Begin Hearings on "Filled Milk" Bill—The Committee on Agriculture of the Senate has begun hearings on the Voigt

filled milk bill, forbidding the shipment in interstate commerce of compounds of skimmed milk and vegetable oil, made in the semblance of whole evaporated milk. Prohibitory and restrictive legislation against these compounds has already been enacted in eleven states of the Union in the interest of public health. The Voigt bill passed the House by a vote of 250 to 40, and is now in the Senate for final consideration.

Tri-State Meeting.—The Medical Society of Virginia, Maryland and the District of Columbia held its spring meeting in Warrenton, Va., May 17, under the presidency of Dr. Stephen Harnsberger of that city. The following officers were elected: president, Dr. William L. Lewis, Kensington, Md.; vice presidents Drs. James H. Ferguson, Clifton Station, Va., and Edmund J. Horgan, Washington, D. C.; recording secretary, Dr. William T. Davis, Washington, D. C.; corresponding secretary, Dr. Joseph D. Rogers, Washington, D. C., and treasurer, Dr. Robert Scott Lamb, Washington, D. C. The next meeting will be held in Washington, D. C., Nov. 15, 1922.

Medical Museums.—The fifteenth annual meeting of the American and Canadian Section of the International Association of Medical Museums was held in the Army Medical Museum, Washington, D. C., in May, under the presidency of Prof. James Ewing of Cornell University. On recommendation of the Council, the Exchange Bureau and the Bureau for the Preservation of the Results of Medical Research of the Section of the Association of Medical Museums were transferred from the McGill University Medical Museum, Montreal, Canada, to the U. S. Army Medical Museum at Washington. Dr. Daniel S. Lamb, assistant and pathologist at the Army Medical Museum from 1865 to 1920, was presented with a testimonial from the U. S. Army Medical Department by Brig.-Gen. Walter D. McCaw, who called attention to the results of his labors as illustrated by the collections of the institution in which the meeting was being held. The *Journal of Technical Methods* (Bulletin 8) and the *Sir William Osler Memorial Bulletin* (Number 9) were ordered published. The following officers were elected for the ensuing year: president, Dr. Frank B. Mallory, Boston, vice presidents, Drs. Howard T. Karsner, Cleveland, Harry Marshall, University, Va., and Robert A. Lambert (Yale University), New Haven, and secretary-treasurer, Dr. Maude E. Abbot (McGill University), Montreal.

Warning on Leprosy.—According to a warning issued by the U. S. Public Health Service, leprosy in the United States is on the increase. Statistics show that there are 1,200 lepers at large in twenty-five states, with the constant danger of communicating the disease to others. Dr. C. H. Lavinder, in explaining the announcement regarding leprosy, said:

> While remarkable results are being obtained in combating leprosy in other countries, it is on the increase in the United States. In the tropics, notably in Hawaii, lepers are being cured by the use of chaulmoogra oil, one of the new discoveries. But we have had no success with it here, owing to the difference in the blood consistency of this climate and of this race. Great Britain long ago decided that the only way to eradicate the disease was to segregate the sufferers, so that there could be no chance for it to be communicated to others. We have adopted such a policy in America and have built a leprosarium at Carville, La. It has room for only 200 patients, and now every available bed is occupied. Each day the government receives applications from lepers seeking admission to the hospital. We pay their transportation and give them the very best of care and attention. But we are compelled to inform health officers who come to us that there is no room. As it is next to impossible for each city to construct its own leprosarium, the sufferers are at large, and each day some one comes in contact with them, adding to the possibilities of the disease being communicated to others.

President Harding, in a recent communication to Congress, asked that sufficient money be appropriated for the enlargement of the leprosarium at Carville. This week Representative Elliott of Indiana and Senator Ransdell of Louisiana introduced bills in the two houses, providing for the appropriation of $650,000 to be used by the U. S. Public Health Service to prevent the spread of leprosy and to provide care and treatment of all persons suffering with leprosy.

Committee to Study Toxicity and Fatalities in Local Anesthesia.—The report of the Board of Trustees of the American Medical Association (THE JOURNAL, May 27, p. 1617) contained an announcement of the appointment of a committee to continue the study of local anesthetics. This committee is composed of representatives from the several sections of the scientific assembly of the American Medical Association and is constituted as follows: representative of surgery, Dr. Elliott C. Cutler, Boston; representative of stomatology, Dr. Henry S. Dunning, New York; pharmacology, Dr. Robert A. Hatcher, New York, secretary of the committee; ophthalmology, Dr. Robert S. Lamb, Washington, D. C.; medicine, Dr. David I. Macht, Baltimore; laryngology, Dr. Emil Mayer, New York, chairman of the committee; pathology, Dr. Charles Norris, New York, and urology, Dr. Alexander Randall, Philadelphia. This new committee proposes to investigate the causes of toxic effects which have followed the use of local anesthetics, with a view to preventing these so far as possible, and thus to increase the safety, value and importance of local anesthesia. The committee requests that Fellows and members of the American Medical Association transmit to the secretary or to one of the members of the committee the information indicated: (1) Have you, during 1920 or 1921, observed any toxic effects—fatal or not—following the use of cocain or any of the other local anesthetics? (2) If you have observed such toxic effects, please submit a detailed report of each case, record, among other facts, data concerning the patient's general condition, the occasion for using the local anesthetic, the drug employed, the method of administration and the dose administered. (3) Kindly inform the committee of the name and address of any physician whom you know to have had any accident with any one of the local anesthetics.

LATIN AMERICA

Children's Bureau in Brazil.—The Department of Public Health of Brazil has created a children's bureau under the direction of Dr. Fernandez Figueira, president of the Brazilian Pediatric Society.

Typhoid Vaccination Introduced in Paraguay.—Dr. Cayetano Masi, surgeon general of the army, has applied to the vaccination of recruits a triple vaccine similar to the one in use in the United States Army. Dr. Masi was in this country last year.

Personal.—Drs. Paulina Luisi and J. C. Brito del Pino will represent Uruguay at the International Congress on Social Hygiene to be held in Paris this year.——Dr. Ciro Leon of Manzanilla, Cuba, has been visiting clinics in this country, especially in Chicago.

Mexican Tribute to Cajal.—At a special meeting of the directing board of the National University of Mexico, it was decided unanimously to grant an honorary diploma to Dr. S. Ramon y Cajal. The Mexican Academy of Medicine has also appointed him an honorary member, disregarding, for the occasion, the usual routine requirements. A subscription started by Dr. T. G. Perrin, the bacteriologist, already amounts to more than $3,000.

Leprosy in Colombia.—According to a recent report by Dr. R. F. Parra, physician in chief of the Agua de Dios Leprosarium, Colombia, there are now 2,726 lepers segregated there. Of these, 122 are receiving chaulmoogra oil treatment. There are two other leprosariums in Colombia, but the facilities are considered insufficient. Dr. Erich Martini is now employed by the government to make a survey of the leprosy situation and present recommendations for its control.

FOREIGN

Psychanalysis for the Poor.—Our Vienna exchanges mention that the Vienna Psychanalysis Society has made arrangements for an hour's evening dispensary for consultation with applicants for psychanalysis and training of physicians in psychanalysis.

Petrina Endowment.—Prof. T. Petrina of Prague, professor emeritus of internal diseases, president of the German section of the Bohemian Medical Society, retired from this and other positions on reaching his eightieth birthday recently. The German-Bohemian members of the society have founded the Petrina Endowment in his honor.

Gullstrand Medal.—The Swedish Medical Association at a recent meeting voted to commemorate the sixtieth birthday of Prof. A. Gullstrand in June with a special medal presenting him with the gold medal and selling the replicas to found a fund in his honor. He was given the Nobel prize in medicine in 1911 for his contributions to the science of ophthalmology, especially the Gullstrand lamp.

The Centennial of a Thesis.—Three French societies combined their efforts and invited the world to help them commemorate the thesis presented by Bayle one hundred years ago to the medical authorities of the University of Paris. Bayle had succeeded in isolating general paresis from the confusion prevailing in his day in regard to nervous and mental disease, and his thesis is a masterly description of the disease and its cause.

The Pioneer in Industrial Hygiene—This is the title bestowed on Dr. B. Ramazzini, the founder of industrial medicine, over two centuries ago (1633-1714). His treatise on "The Diseases of Artificers," was translated into English in 1750. He studied at the University of Padua which has recently celebrated its septicentennial, and commemorative addresses on Ramazzini have been delivered in several Italian cities as part of the septicentennial ceremonies.

New Medical Society—The inaugural meeting of the Cambridge University Medical Society was held in the Anatomy School, Cambridge, England, May 10. Dr. W. Langdon Brown of St. Bartholomew's Hospital, London, was the lecturer and spoke on "The Endocrine Glands and Their Relationship to the Sympathetic Nervous System." The following are the officers of the society: president, Mr. E. S. Fellowes-Farrow; vice president, Mr. Norman F. C. Burgess; secretary, Mr. C. L. Owen, and treasurer, Mr. T. F. McNair Scott.

Total of Arsphenamin Fatalities—The antiarsphenamin agitation in Germany, which was mentioned last week on page 1974, has brought out the fact that the proportion of mishaps with arsphenamin treatment amounts to about 1: 10,000. This statement was made by Professor Jadassohn and Professor Galewski in testifying before the committee appointed by the reichstag to investigate the matter. They presented evidence further to show that with anesthetics the ratio of mishaps was 1: 4,000 not so long ago, and it is now fully 1: 10,000. They said that the aim should be not to restrict the use of the arsenicals but to train physicians in their use.

The Padua Septicentennial—Among the students who flocked to the University of Padua were Vesalius who came from Brussels, William Harvey, who came from England to describe the circulation of the blood, Ariosto, Tasso, Copernicus and Benner. The souvenir medal struck off bears the heads of Morgagni and Galileo. The *Riforma Medica* gives an illustrated description of the festivities and relates that the first anatomy amphitheater was at Padua (1490), and the first chair of clinical medicine was organized in 1543. This was 105 years before Leyden could boast a chair of the kind. Four hundred delegates from various countries and scientific organizations took part in the proceedings, with the king of Italy and the scientific authorities of the land. A bronze bust of the late Prof. A. De Giovanni was also unveiled.

Personal—Professor Weygandt of Hamburg delivered an address recently at Rome on "Psychology in Art," on the invitation of the medical faculty.——Professor Kolle of Frankfort-on-the-Main was invited to lecture at the medical school at Budapest on the "Present Status of Serotherapy and Chemotherapy."——Professor Siebenmann of the chair for ear and throat diseases at Basel was feted on the occasion of his seventieth birthday, recently, and the *Schweizerische medizinische Wochenschrift* published a special number in his honor.——The Prussian Academy of Sciences has granted an appropriation to Prof. D. Ackermann to aid in continuing his research on the extractive substances of nonvertebrates and to Dr. Paula Hertwig for continuing her experimental research on heredity, with 2,000 marks to Dr. F. Levy for his research on the physiology of cell segmentation.

Deaths in Other Countries

Dr. **L. Jeanneret**, a pediatrician of Lausanne.——Dr. **Wilmart** of Brussels.——Dr. **Virgilio Manzanares** of San Miguel, San Salvador.——Dr. **P. Mazzeo**, instructor in pediatrics at the University of Naples.——Dr. **Saint-Hubert Serre** of the medical faculty at Montpellier.——Dr. **Schlange**, chief of the surgical service at the Hannover city hospital, aged 66.——Dr. **George D. Wilson**, vice president of the National Medical Union, and former chairman of the British Medical Association, Wandsworth Division, died in London, May 1.——Col. **Michael J. Sexton**, served in the Burmese War, the South African War and the late war with the R. A. M. C., died at Herne Bay, England, aged 61.——Lieut.-Col. **C. W. Owens**, R. A. M. C., served in three wars and as surgeon to the late Lord Roberts in India, justice of the peace, died, May 23, aged 69.

CORRECTION

Portrait for University of Pennsylvania.—In THE JOURNAL, June 24, p. 1971, it was stated that a portrait of Dr. Fussell was presented to the university by members of the faculty of the medical school. Dr. James M. Anders, Philadelphia, writes that the contributions for the portrait were made by Dr. Fussell's many friends and former medical students.

Government Services

Army Personnel

By the adoption of the conference report by the two houses of Congress, on the Army appropriation bill, all promotions in the Army below the grade of colonel will cease for the next six months. The provision in the bill applies to all branches of the service, including the medical department. The measure as finally agreed upon fixes the size of the Army at 12,000 officers and 125,000 enlisted men. Reduction of the officers' personnel from its present strength to 12,000 will be effected through the appointment of a selection board whose duty it shall be to review the efficiency of all the officers of the Army and recommend those for discharge or retirement who have failed to make satisfactory officers. The medical department will not be materially affected by the commissioned personnel reduction, as the number of its officers at the present time is below the quota.

Bureau Representative to Investigate European Conditions

Major Leon Fraser, assistant director of the U. S. Veterans' Bureau, sailed, June 24, on the *America* for the purpose of making a survey of conditions affecting the disabled beneficiaries of the bureau in England, France, Belgium, Germany, Austria, Switzerland, Italy and Greece. The bureau has 15,000 insurance and compensation beneficiaries in Europe, receiving more than $600,000 every month, and is at present attempting to handle the situation through American consuls.

Graduation at Army Medical School

General Pershing presented diplomas to the graduates of the Army Medical School at the commencement exercises. Brig.-Gen. Walter D. McCaw, a member of the staff of the Surgeon-General of the Army, delivered the address, in which he praised the members of the Medical Corps for the work accomplished during the World War. Those receiving diplomas were:

Honor Men—Capt. Albert Bowen, Capt. Raymond O. Dart (Sternberg medal), Capt. Arthur D. Haverstock, Capt. John R. Herrick, Capt. Howard J. Hutter, Capt. Douglas H. Mebane, Capt. William C. Pollock (Hoff medal).

Graduates—Major Robert A. Hale, Major William G. McKay, Capt. William B. Blacksmare, Capt. James M. Bryant, Capt. Harry A. Clark, Capt. Joseph S. Craig, Capt. Arthur W. Drew, Capt. John F. Edwards, Capt. William B. Foster, Jr., Capt. Claude V. Gautier, Capt. Emory H. Gist, Capt. Sam Hardeman, Capt. George R. Harris, Jr., Capt. Clarence C. Harvey, Capt. Leonard W. Hassett, Capt. Adam G. Heilman, Capt. Jarrett M. Huddleston, Capt. James R. Hudnall, Capt. Francis B. Hutton, Jr., Capt. Charles H. Irving, Capt. Julius A. Johnson, Capt. John F. Lieberman, Capt. Merrill K. Lindsay, Capt. William D. McClelland, Capt. John I. Meagher, Capt. Joseph A. Mendelson, Capt. William J. Miehe, Capt. Frank McA. Moose, Capt. Charles R. Mueller, Jr., Capt. Cyrenius A. Newcomb, Capt. James A. Orbison, Capt. David L. Robeson, Capt. John L. Robinson, Capt. Myron P. Rudolph, Capt. Montraville A. St. Peter, Capt. John M. Tamraz, Capt. Robert E. Thomas, Capt. Anthony J. Vadala, Capt. Logan M. Weaver, First Lieut. George F. Cooper (Slee Medal), First Lieut. Walter C. Rovals, First Lieut. George P. Sandrock, First Lieut. William LeR. Thompson.

Citizens' Training Camps

Improvement in the health of the youth of the country is one of the prime results to be sought by the Citizens' Military Training Camps, which are to be held throughout the United States by the War Department during July and August. Full information as to entrance requirements, including application blanks, may be obtained from corps area commanders, nine of whom are located at various points in the country, as follows:

First Corps Area, Boston, includes Maine, New Hampshire, Vermont, Massachusetts, Rhode Island and Connecticut.

Second Corps Area, Governors Island, N. Y., includes New York, New Jersey and Delaware.

Third Corps Area, Fort Howard, Md., includes Pennsylvania, Maryland, District of Columbia and Virginia.

Fourth Corps Area, Fort McPherson, Ga., includes North Carolina, South Carolina, Georgia, Florida, Alabama, Tennessee, Mississippi and Louisiana.

Firth Corps Area, Fort Benjamin Harrison, Ind., includes Indiana, Ohio, West Virginia and Kentucky.

Sixth Corps Area, 1819 W. Pershing Rd., Chicago, Ill., includes Illinois, Michigan and Wisconsin.

Seventh Corps Area, Fort Crook, Neb., includes North Dakota, South Dakota, Minnesota, Nebraska, Iowa, Kansas, Missouri and Arkansas.

Eighth Corps Area, Fort Sam Houston, Texas, includes Texas, New Mexico, Colorado, Oklahoma and Arizona.

Ninth Corps Area, San Francisco, includes Washington, Oregon, Idaho, Montana, Wyoming, Utah, Nevada and California.

Fatal Poisoning with Naphthol Salve

At a recent session of the Therapeutic Society, Dr H Busquet related that a 5-weeks-old babe, who had a gluteal hema and excoriation, had been treated by its mother with naphthol pomade, on his advice Besides naphthol, the salve contained sulphur and menthol, which did not have any part in the poisoning The total amount used in two munctions in twenty-four hours was 10 gm, corresponding to 1 gm of naphthol A few hours after the second application, pallor and acceleration of the pulse were noticed The next day, jaundice appeared, followed by cyanosis of the lips diarrhea, vomiting and scanty urine with albumin The following day the child was in coma and death occurred with a temperature of 35 7 C (96 3 F) In the course of the discussion concerning this communication, Artault remarked that products formed by alteration of naphthol are more toxic than naphthol itself Thus, it is important to keep naphthol in well stoppered bottles, sheltered from light, and it is still better to use a fresh product Richaud and Desesquelle emphasized the ease of absorption of phenol products when the skin is not intact, as in Busquet's case

Illegal Practice of Medicine by a Truss Maker

Is a truss maker, not a physician, who sells his apparatus regularly in certain territories, guilty of illegal practice of medicine? As a rule, the courts have decided in his favor when the truss maker confines himself to the sale of his apparatus and the taking of measurements, without making a diagnosis or treating the affection In this case, the truss maker must not question the patient on his health condition or examine him, either to make a diagnosis or to give him the necessary truss Apparatus must be made at the order of a physician only He is considered as practicing medicine illegally if he tells the patient that, with his apparatus, he can be cured within a certain time, or if he dissuades the patient from having an operation considered necessary by a physician, and that he claims to prevent by the use of his apparatus The *Concours medical* publishes a case of this kind in which the truss maker guaranteed a complete cure to his patient in two years, and made him sign a contract for the purchase of his apparatus But the patient consulted a physician, who diagnosed the case as hydrocele. Thus the truss maker's diagnosis was detrimental to the patient, who was obliged to purchase from him an apparatus not only expensive but also harmful, which might have increased his suffering

Memorial to the Army Medical Service of the World War

A ceremony was held recently at the Ecole d'application de medecine et de pharmacie militaires at Val-de-Grace in memory of the officers and soldiers of the medical corps who died during the World War The minister of war, who spoke in behalf of the government, said that homage must be paid to civilian physicians who enlisted during the war, as well as to regular army physicians The ceremony was presided over by the president of the republic, and Mme Millerand placed a wreath at the base of the bronze monument 'In the Mud of the Somme," which symbolizes the devotion of the stretcher bearers

Propaganda Against Conception

In a preceding letter (THE JOURNAL, March 5 1921, p 666) I mentioned the law against enticement to abortion and the propaganda against conception The attorney-general of Nantes made use of this law against a storekeeper who had sold or exhibited for sale instruments and articles to prevent conception But, notwithstanding the fact that the goods had been exhibited in the store window of the accused, the Nantes court did not agree with the attorney-general, and acquitted the man, stating that

> No law prevents at the present time the manufacture sale or exhibition of instruments or articles to prevent conception and although the accused offered these instruments or articles for sale there is no actual intent or advertising showing that by exhibiting them he intended to carry on a propaganda against conception Thus the essential element of the offense is lacking and there *is no* legal basis for accusation

Creation of Two Chairs of Hydrology and Climatology

A chair of therapeutic hydrology and climatology has been created in the faculties of medicine and pharmacy of the universities of Bordeaux and Toulouse

War Cross Awarded to the Val-de-Grâce School

At the end of the ceremony mentioned in the previous paragraph, the president of the republic stated that the ministry of war had awarded the Croix de guerre to the school of Val de-Grace with the citation

> True to its noble traditions the school of applied medicine and pharmacy of the army inspired the officers of the medical corps with the cult of science and the spirit of sacrifice and by the admirable devotion and abnegation shown by them during the World War, they merited everlasting homage from the country

LONDON

(From Our Regular Correspondent)

June 12, 1922

Death of William Halse Rivers

Through the recent death of Dr William Halse Rivers, M D F R C P F R S, president of the Anthropological Society, at the age of 56, following an acute abdominal illness, a brilliant and subtle mind, which had shed great light on the difficult problems of race, has been lost

He was educated at St Bartholomew's Hospital, and graduated with an M B degree at the London University, in 1886 He became house physician at the National Hospital for the Paralysed and Epileptic, and, at an early age, was lecturer on psychology at Guy's Hospital and on experimental psychology at the University of Cambridge He attained the degree of F R C P in 1899 He delivered the Croonian lectures on fatigue and the action of drugs in 1906 and the Fitzpatrick lectures on medicine, magic and religion in 1915 and 1916 But it was as an anthropologist that he first achieved wide fame He was a member of the Cambridge expedition to the Torres Straits and wrote a book in two volumes entitled the History of Melanesian Society," in which he made a bold attempt to reconstruct the history of the migrations of the Melanesians from their culture The work was a contribution to comparative ethnology, remarkable for both its original research and its scrupulous accuracy Other anthropologic works were Kinship and Social Organization and The Todas ' Then came the period in which he turned his attention to psychology and the writings of Freud of whom he might be described as a critical follower He considered that Freud insisted unduly on the sex instinct In 1920 he published 'Instinct and the Unconscious" which he described as a contribution to a biologic theory of the psychoneuroses ' It embodied his life studies and his experience with soldiers who had broken down under the strain of the war

His special aim was to study the relation between instinct and the body of experience we are accustomed to speak of as the unconscious ' The discovery of Head that in the healing of a severed cutaneous nerve there are two stages of sensibility—protopathic and epicritic—he explained as representing different stages in the development of the afferent nervous system Certain manifestations of protopathic sensi-

Those receiving diplomas were:

Honor Men—Capt. Albert Bowen, Capt. Raymond O. Dart (Sternberg medal), Capt. Arthur D. Haverstock, Capt. John R. Herrick, Capt. Howard J. Hutter, Capt. Douglas H. Mebane, Capt. William C. Pollock (Hoff medal).

Graduates—Major Robert A. Hale, Major William G. McKay, Capt. William B. Blacksnare, Capt. James M. Bryant, Capt. Harry A. Clark, Capt. Joseph S. Craig, Capt. Arthur W. Drew, Capt. John F. Edwards, Capt. William B. Foster, Jr., Capt. Claude V. Gautier, Capt. Emory H. Gist, Capt. Sam Hardeman, Capt. George R. Harris, Jr., Capt. Clarence C. Harvey, Capt. Leonard W. Hassett, Capt. Adam G. Heilman, Capt. Jarrett M. Huddleston, Capt. James R. Hudnall, Capt. Francis B. Hutton, Jr., Capt. Charles H. Irving, Capt. Julius A. Johnson, Capt. John F. Lieberman, Capt. Merrill K. Lindsay, Capt. William D. McClelland, Capt. John I. Meagher, Capt. Joseph A. Mendelson, Capt. William J. Miehe, Capt. Frank McA. Moose, Capt. Charles R. Mueller, Jr., Capt. Cyrenius A. Newcomb, Capt. James A. Orbison, Capt. David L. Robeson, Capt. John E. Robinson, Capt. Myron P. Rudolph, Capt. Montraville A. St. Peter, Capt. John M. Tamraz, Capt. Robert E. Thomas, Capt. Anthony J. Vidala, Capt. Logan M. Weaver, First Lieut. George F. Cooper (Slee Medal), First Lieut. Walter C. Rovals, First Lieut. George P. Sandrock, First Lieut. William LeR. Thompson.

Citizens' Training Camps

Improvement in the health of the youth of the country is one of the prime results to be sought by the Citizens' Military Training Camps which are to be held throughout the United States by the War Department during July and August. Full information as to entrance requirements including application blanks, may be obtained from corps area commanders, nine of whom are located at various points in the country, as follows:

First Corps Area, Boston, includes Maine, New Hampshire, Vermont, Massachusetts, Rhode Island and Connecticut.

Second Corps Area, Governors Island, N. Y., includes New York, New Jersey and Delaware.

Third Corps Area, Fort Howard, Md., includes Pennsylvania, Maryland, District of Columbia and Virginia.

Fourth Corps Area, Fort McPherson, Ga., includes North Carolina, South Carolina, Georgia, Florida, Alabama, Tennessee, Mississippi and Louisiana.

Firth Corps Area, Fort Benjamin Harrison, Ind., includes Indiana, Ohio, West Virginia and Kentucky.

Sixth Corps Area, 1819 W. Pershing Rd., Chicago, Ill., includes Illinois, Michigan and Wisconsin.

Seventh Corps Area, Fort Crook, Neb., includes North Dakota, South Dakota, Minnesota, Nebraska, Iowa, Kansas, Missouri and Arkansas.

Eighth Corps Area, Fort Sam Houston, Texas, includes Texas, New Mexico, Colorado, Oklahoma and Arizona.

Ninth Corps Area, San Francisco, includes Washington, Oregon, Idaho, Montana, Wyoming, Utah, Nevada and California.

Fatal Poisoning with Naphthol Salve

At a recent session of the Therapeutic Society, Dr H Busquet related that a 5-weeks old babe, who had a glutеal eczema and excoriation, had been treated by its mother with naphthol pomade, on his advice Besides naphthol, the salve contained sulphur and menthol, which did not have any part in the poisoning The total amount used in two munctions in twenty-four hours was 10 gm, corresponding to 1 gm of naphthol A few hours after the second application, pallor and acceleration of the pulse were noticed The next day, jaundice appeared, followed by cyanosis of the lips diarrhea, vomiting and scanty urine with albumin The following day the child was in coma and death occurred with a temperature of 35 7 C (96 3 F) In the course of the discussion concerning this communication, Artault remarked that products formed by alteration of naphthol are more toxic than naphthol itself Thus, it is important to keep naphthol in well-stoppered bottles, sheltered from light, and it is still better to use a fresh product Richaud and Desesquelle emphasized the ease of absorption of phenol products when the skin is not intact, as in Busquet's case

Illegal Practice of Medicine by a Truss Maker

Is a truss maker, not a physician, who sells his apparatus regularly in certain territories, guilty of illegal practice of medicine? As a rule, the courts have decided in his favor when the truss maker confines himself to the sale of his apparatus and the taking of measurements without making a diagnosis or treating the affection In this case, the truss maker must not question the patient on his health condition or examine him either to make a diagnosis or to give him the necessary truss Apparatus must be made at the order of a physician only He is considered as practicing medicine illegally if he tells the patient that, with his apparatus, he can be cured within a certain time, or if he dissuades the patient from having an operation considered necessary by a physician, and that he claims to prevent by the use of his apparatus The *Concours medical* publishes a case of this kind in which the truss maker guaranteed a complete cure to his patient in two years, and made him sign a contract for the purchase of his apparatus But the patient consulted a physician, who diagnosed the case as hydrocele Thus, the truss maker's diagnosis was detrimental to the patient, who was obliged to purchase from him an apparatus not only expensive but also harmful, which might have increased his suffering

Memorial to the Army Medical Service of the World War

A ceremony was held recently at the Ecole d application de medecine et de pharmacie militaires at Val-de-Grace in memory of the officers and soldiers of the medical corps who died during the World War The minister of war who spoke in behalf of the government, said that homage must be paid to civilian physicians who enlisted during the war, as well as to regular army physicians The ceremony was presided over by the president of the republic, and Mme Millerand placed a wreath at the base of the bronze monument 'In the Mud of the Somme," which symbolizes the devotion of the stretcher bearers

Propaganda Against Conception

In a preceding letter (THE JOURNAL, March 5, 1921, p 666) I mentioned the law against enticement to abortion and the propaganda against conception The attorney-general of Nantes made use of this law against a storekeeper who had sold or exhibited for sale instruments and articles to prevent conception But, notwithstanding the fact that the goods had been exhibited in the store window of the accused, the Nantes court did not agree with the attorney-general, and acquitted the man, stating that

> No law prevents, at the present time the manufacture sale or exhibition of instruments or articles to prevent conception and although the accused offered these instruments or articles for sale there is no act plot intent or advertising showing that by exhibiting them, he intended to carry on a propaganda against conception Thus the essential element of the offense is lacking and there is no legal basis for accusation

Creation of Two Chairs of Hydrology and Climatology

A chair of therapeutic hydrology and climatology has been created in the faculties of medicine and pharmacy of the universities of Bordeaux and Toulouse

War Cross Awarded to the Val-de-Grâce School

At the end of the ceremony mentioned in the previous paragraph, the president of the republic stated that the ministry of war had awarded the Croix de guerre to the school of Val-de-Grace with the citation

> True to its noble traditions the school of applied medicine and pharmacy of the army inspired the officers of the medical corps with the cult of science and the spirit of sacrifice and by the admirable devotion and abnegation shown by them during the World War they merited everlasting homage from the country

June 12, 1922

Death of William Halse Rivers

Through the recent death of Dr William Halse Rivers, M D, F R C P F R S, president of the Anthropological Society, at the age of 56, following an acute abdominal illness, a brilliant and subtle mind, which had shed great light on the difficult problems of race, has been lost

He was educated at St Bartholomew's Hospital and graduated with an M B degree at the London University, in 1886 He became house physician at the National Hospital for the Paralysed and Epileptic, and, at an early age, was lecturer on psychology at Guy's Hospital and on experimental psychology at the University of Cambridge He attained the degree of F R C P in 1899 He delivered the Croonian lectures on fatigue and the action of drugs in 1906 and the Fitzpatrick lectures on medicine, magic and religion in 1915 and 1916 But it was as an anthropologist that he first achieved wide fame He was a member of the Cambridge expedition to the Torres Straits and wrote a book in two volumes entitled the History of Melanesian Society," in which he made a bold attempt to reconstruct the history of the migrations of the Melanesians from their culture The work was a contribution to comparative ethnology, remarkable for both its original research and its scrupulous accuracy Other anthropologic works were 'Kinship and Social Organization and The Todas" Then came the period in which he turned his attention to psychology and the writings of Freud of whom he might be described as a critical follower He considered that Freud insisted unduly on the sex instinct In 1920 he published 'Instinct and the Unconscious,' which he described as 'a contribution to a biologic theory of the psychoneuroses" It embodied his life studies and his experience with soldiers who had broken down under the strain of the war

His special aim was to study the relation between instinct and the body of experience we are accustomed to speak of as the unconscious" The discovery of Head that in the healing of a severed cutaneous nerve there are two stages of sensibility—protopathic and epicritic—he explained as representing different stages in the development of the afferent nervous system Certain manifestations of protopathic sensi-

bility are suppressed as belonging to a crude form of nervous system, which has been superseded by a more efficient mechanism The suppressed reactions are ready to spring into activity whenever the situation calls for an emotional rather than an intellectual response From these considerations follows the argument that "the suppression of conscious experience is only one example of a process which applies throughout the animal kingdom and is essential to the proper regulation of every form of human or animal activity Every living process of the animal involves not only activity devoted to the special end to be met but also the inhibition of activities of other kinds" Certain elements of early experience are utilized and form, by fusion with other elements, the products which make up the experience of later life Elements which are incompatible with later developments are suppressed

Rivers restricted the term "unconscious" to the earlier forms of mental experience which have not been utilized by the process of fusion Much, however, of the unconscious he regarded as such, on account of its having accompanied a painful experience Hysteria he held to be essentially protective Cases met during the war had the common feature that they unfitted the subject for further participation in warfare The symptoms appeared in order to 'protect" the individual Thus was the immemorial conflict between instinct and duty solved By the premature death of Rivers, morbid psychology has lost its most philosophical mind since Hughlings Jackson

The Reprieve of Ronald True

The case of Ronald True, who was sentenced to death for the murder of a courtesan has been reported in previous letters (THE JOURNAL, May 27, p 1651, June 17, p 1907) In spite of the unanimous evidence of the physicians, including those in the jail service that he was insane the jury found him guilty of murder and responsible for the act, and the court of appeal confirmed the verdict The home secretary ordered an inquiry into his mental condition by three experts They unanimously pronounced him insane He was therefore reprieved and sent to a criminal lunatic asylum The reprieve has provoked an unprecedented storm of protest in the press and in journals of all shades of political opinion The prisoner's disreputable career and the callous brutality of the crime with the sordid motive of theft caused a strong desire to see justice done The fact that the jury rejected the plea of insanity was considered decisive on that point

In charging the grand jury at the Devon assizes, the judge (Mr Justice Avory) said, referring to the lightness of the calendar "I hope this may be taken as a symptom that a recrudescence of crime which we experienced after the war is abating Whether it will continue to abate if the infliction of the penalties of the law is to be left to the discretion of experts in Harley Street, I very much doubt, for the only real deterrent to crime is the certainty that the appropriate penalty will follow its commission' This slogan, 'Trial by Harley Street" (the principal physicians' street in London), has been taken up by the press The whole trouble turns on the difference between the legal and the medical conception of insanity which is a constant bone of contention in the courts In this case, notwithstanding the medical evidence, the jury refused to find the prisoner legally insane On the other hand, the committee of experts had not to determine the question of criminal responsibility but whether the prisoner was insane at the time of their examination It having been determined that he was insane he could not be executed, for the law forbids the execution of an insane man But so great was the indignation that the press and public lost sight of these facts, which show that the home secretary had no choice in the matter but was bound to act as he has done He was assailed with the greatest virulence and has had to defend himself in Parliament Even the unfounded allegation was made that True had got off because he had relatives high in society

Another aspect of the case is put by a well-known admiral, who says "Whether he is a lunatic or not, why should the taxpayer pay to keep in existence a man who brutally murders a woman in order to steal her jewelry? Murderers had better be tried by a naval court-martial We should expend a few pence more in rope, but save the country many thousands of pounds in lunatic asylums" The press declares that mental experts have become imbued with Freudian and other recent doctrines to the extent of extinguishing human responsibility for anything and that they have come to regard brutal crimes as a symptom of insanity If they are to gain a footing at the home office murder trials will become a mockery, and our criminal lunatic asylums will become overcrowded unless, indeed, they demand a general jail delivery on psychologic grounds

An American Surgeon in Charge at a London Hospital

Dr Harvey Cushing professor of surgery in Harvard University is on the invitation of the governors and of the medical college of St Bartholomew s Hospital, acting as director of the surgical professorial unit A similar compliment was paid last year, when the director of the surgical professorial unit of the hospital acted as temporary surgeon-in-chief of the Peter Bent Brigham Hospital in Boston The interchange of teachers between our medical schools and those of America has sprung from the intimacy and consequent mutual appreciation which was brought about in the war Professor Cushing was created a Companion of the Order of the Bath for his services with the British Forces in France, and was elected an Honorary Fellow of the Royal College of Surgeons of England

Tropical Research in East Africa

It is proposed that the research station at Amani in German East Africa which in the days before the war was reputed to be one of the leading tropical research institutions in the world, shall be made the central research station for the whole of East Africa During hostilities, the Germans produced there huge stores of food and other supplies including 15 000 bottles of "whisky," and soap, candles and medicines.

The Increase of Cancer

As stated in a previous letter (THE JOURNAL, June 24 p 1975) the increase of cancer has again become a topic of interest Our ignorance as to the cause of the disease is reflected in the diverse suggestions which are being made in the press in some cases by distinguished scientists Tea drinking the cooking of food the inhalation of tar dust arising from roads, microbes which are generated in drinking water stored in reservoirs have been in turn incriminated The proportional mortality from the disease is shown by the following figures, given in the last census of England and Wales for the deaths from the principal diseases per thousand deaths cancer 68, phthisis 74 3, nervous diseases 107 4, bronchitis and pneumonia, 140 7, heart disease, 85, violence, 38 5

Knighthood Conferred on a "Bone Setter"

Mr H A Barker, the "bone setter," has been knighted He is described officially as 'a specialist in manipulative surgery who placed his manual dexterity unreservedly at the disposal of all wounded ex-service men' Though not a qualified member of the medical profession, he enjoyed an extensive and fashionable practice and for long was a cause of acrimonious controversy A physician had his name removed from the register for administering anesthetics for him He possesses considerable manipulative skill, for he won the approval of some leading surgeons, but how far the

absence of the regular training led him to adopt "manipulative surgery" in cases in which it did no good or even did positive harm is a question on which we have no light Some time ago, an attempt was made, as stated in THE JOURNAL, by his influential friends to obtain for him an honorary medical qualification, but it failed The rather absurd reason was given that the fact that he had not a qualification prevented him from explaining his methods to the profession We have to go back to the days of Queen Anne for an instance of a man outside the profession being given a knighthood for supposed medical skill She conferred this honor on her oculist, who was unqualified and is regarded as a quack

BELGIUM

May 27, 1922

The Reserve Medical Corps

The minister of national defense recently submitted to the king a decree concerning the creation of a school whose duty will be (1) to give or to perfect professional instruction to officers, future reserve officers noncommissioned officers and certain soldiers in the sanitary service, (2) to experiment with field equipment and to study the operation of the sanitary service, and (3) to give special instruction as ambulance bearers to men preparing for ecclesiastical duties The school will include a staff, a school for reserve physicians and pharmacists, a company of ambulance bearers and an executive staff The aim of the school is to train the men in the militia who intend to become physicians or pharmacists in the professional technic of the army, and to give them the necessary military instruction and education to prepare them to fulfil, after their university studies, the functions of reserve physicians or pharmacists, and to enable them, in the interval, to render service in the field, thus insuring a sanitary service with a complete force at all times

Congenital Upward Displacement of the Scapula

Dr Delchef presented to the Academy of Medicine two curious cases constituting actual ectopia of the scapula The malformation is analogous to an arrest of the ascent of one or both ilia with six sacral vertebrae and has the same clinical significance as cervical ribs The abnormal bone parts holding the scapula to the vertebrae are not the cause of the malformation, but a complication probably of vertebral origin The hypothesis of a regressive anomaly, with a resemblance to the complete scapular girdle of certain fish is not justified On the other hand, the resemblance to a cervical rib seems justified, but the extreme difference between the anatomic anomalies increases the doubt as to the pathogenesis Operative intervention is indicated when the fixity of the scapula entails important functional disturbances The operation consists, according to cases in resection either of the superior internal angle of the elongated and curved bone, or of the supernumerary bone parts and dividing the retracted muscular fibers It may be necessary, besides, to raise the muscles on the inward edge or to fasten the scapula to the ribs, spine or muscle

Protection of Children Against Tuberculosis

Monsieur Duthoit has published his report concerning the activity of the society for the protection of children against tuberculosis during 1920 The work is accomplished with the cooperation of the Belgian national league against tuberculosis Its dispensaries send to the society children of the patients frequenting their consultations, who are accepted only on a report from the dispensary physician and the prophylaxis nurse The society includes at present, the Edith Cavell infant shelter, twelve cradles, the Berthemlez-Louvain colony, thirty beds, and the Flobecq colony, with 130 children The "Foyer Elizabeth" was organized in the Flobecq colony, in 1920, to isolate and give special care to children who become ill while out to nurse, and to quarantine those coming from Brussels before they were turned over to the nurses The total number of days of care in the three establishments in 1920 was 40,130, for an average of 167 children The upkeep for each child has been 3 48 francs each day

Pneumococcus Infection and the Congo Troops

Dr Lejeune recently submitted a report to the Belgian Society of Tropical Medicine concerning some interesting statistics on the morbidity of black troops The figures show that in German East Africa, in 1917, only 25 per cent of the deaths were due to the enemy fire During this campaign, pneumococcic infections alone killed 4 per cent more men than bullets did Negroes do not seem to be able to resist the pneumococcus, and the reason for this is not clear Senegalese troops in France showed that the race factor was not the only cause for, after a few months, by degrees they became spontaneously immunized There was an average loss of 6 per cent at the beginning, but later the black troops became as resistant as European troops Lejeune called the attention of the civil and military authorities to the advantages that would be derived from compulsory vaccination of postoffice employees, soldiers and workmen Antipneumococcic vaccines and serums should be put at the disposal of all physicians in the colony, and, if possible, they should be manufactured in various parts of the Congo under the same conditions as smallpox vaccine

Reform of Medical Studies

We mentioned in a previous letter the discussions pertaining to the reform of medical studies Notwithstanding the differences of opinion, members of the Academy of Medicine have finally arrived at an understanding Medical studies in universities must be of seven years' duration This includes all scientific and medical studies for the degree of doctor of medicine

Anthropometry of the Belgian Woman

Monsieur Gilet has submitted to the Societe d'Anthropologie of Brussels the results of his inquiry concerning the anthropometry of Belgian women His researches were made on 1 000 delinquent women and 400 nondelinquent women He concludes that the proportion of Belgian women whose weight corresponds to their height is very small Social conditions and temperaments have an influence on this He remarks that the muscular type of woman is best, but is rarely found in Belgium, because, on account of education, atavism or indifference, she neglects physical instruction and the improvement of her constitution Developing exercises should be applied equally to the two sexes, and athletic sports would be of great advantage to women

BUCHAREST

Imbecility in Its Clinical and Medicolegal Aspects

At a recent meeting of the Medical Society of Bucharest, Dr Popescu read a paper on imbecility in its clinical and medicolegal aspects He considered that particular form of imbecility described as moral insanity or moral imbecility The symptoms to which he assigned the foremost place were lack of discretion, absolute incapacity for being influenced strong criminal propensity traceable even to childhood, lifelong instability and restlessness, aversion to useful employment unsociableness, exaggerated self-esteem, excessive fancifulness, vanity, egotism complete want of ethical ideas and impulses, absolute unconsciousness of justice and moral-

ity, and a great many bodily signs of degeneration Heredity had something to do with the development of these defects Observations extending over many years had convinced Dr Popescu that the ethical imperfections enumerated in this list and the criminal acts arising from them were the results of mental incapacity dating from the earliest period of life In all patients whom he had the opportunity of observing from the age of 10 or 12 years to full maturity, he found that the ethical shortcomings which rendered them useless as members of society showed no tendency to increase He then described those forms of the disease which present similar symptoms and might therefore be confused with moral imbecility, called attention to the chief points serving to distinguish them, made some observations on the prognosis, discussed the general question of how such cases should be dealt with, and devoted a few words to the subject of judicial decisions He agreed with other continental neurologists that this form of mental abnormality presented certain features which were always similar and decidedly characteristic, as already mentioned, the features in question existed from the *earliest period of life and showed no tendency to increase*, and, on account of possessing these qualities, the condition now described might be reckoned as one of the special or definite types of mental disease

Poisoning with Methylated Gin

A series of cases of poisoning was reported to the health authorities in Sofia recently and in subsequent investigations some unexpected disclosures were made Within a few days, seven cases of illness, all presenting similar symptoms, were observed in a Bulgarian mining district, and, in a Sofia suburb, about forty persons were attacked with marked drowsiness, vomiting and violent muscular cramps That the condition was a result of poisoning by methylated gin was ascertained in the Sofia cases only after the source of the fatal cases had been discovered in the mining district Altogether about 1,800 liters (450 gallons) of the poisonous gin has been seized and destroyed, and endeavors are being made to trace the buyers of other quantities of liquor How the methyl alcohol has found its way into the gin could not be ascertained This is the first instance, in Bulgaria, in which an alcoholic beverage containing dangerous admixtures has escaped detection by the excise and the health officers

The Feebleminded

The truth about the feebleminded is gradually being put in plain words before the public and at a recent meeting of the Kolozsvar education committee Dr A Elfer spoke very forcibly regarding the necessity for legislation giving legal control over those unable to take care of themselves In moving the adoption of the report of the special schools after-care committee, Dr Elfer stated that, while the children improved very much in the school, when they were turned out into the world only 5 per cent proved capable of earning the minimum for maintenance and many who when they first left school became wage earners fell back into the class of unemployed The experience of the after-care committee has led Dr Elfer to the conclusion that the mentally defective require life-long control, some to a greater and some to a less extent, but such control must be provided, or the work spent on them during their earlier years will be entirely wasted

Spontaneous Fracture of the Ribs in a Syphilitic Patient

The Sarajevo County Hospital reports the case of a woman, aged 41, who presented several unusual symptoms of syphilitic origin She had contracted the infection fourteen years before, and had been treated with injections of mercuric salicylate Since that time she had remained free from all symptoms until a few months *previously when suddenly* an infiltration of the sternal extremity of the right clavicle appeared and developed into a well defined, immovable tumor, which still existed Two months previously, a similar nodule had appeared on the sternum and four weeks later a fresh tumor was observed, but this time on the eighth right rib in the posterior axillary line The nodule was hard, immovable and very tender The patient said that when bending to the side she suddenly felt a sharp pain and a cracking noise on the side of the new tumor Since that time, she had felt pain at this point on coughing, turning or breathing deeply An examination by the roentgen rays revealed the true nature of the affection The roentgenogram revealed a fracture of the rib the vertebral fragment having two sharp points and the sternal fragment being distant about 1 5 cm from the other portion The rib itself was thickened and the periosteum was infiltrated (gummatous osteomyelitis and periostitis) Cases of such spontaneous fractures are very rare

PRAGUE

(From Our Regular Correspondent)

June 1, 1922

Congress of University Teachers

A general congress of Czechoslovak university teachers was held in Prague, May 14-16 The congress was attended by about 500 members The congress was opened by the president Masaryk, who was at one time a professor of philosophy at Prague University In the section on educational questions Prof Jaroslav Hlava, senior on the staff of Prague medical faculty, presented a scheme for the reform of medical studies in the republic The theoretical study should last according to his plan for five years, as has been the case up to date He reserves two years for the study of chemistry, biology physics, anatomy histology and physiology as has been done in the past adding to these fundamental sciences, microbiology as a special subject Under the present plan the students have to pass the examinations in these sciences at the end of the second year Professor Hlava would give the examinations in the first four semesters He also desires to have all the semesters equally long At the present time the winter semester is almost twice as long as the summer semester The most radical changes which he suggests concern the second part of the medical course in the last four years To the examinations in twelve different topics which the medical students have to undergo he adds six He wishes to have included among the new topics public health administration and social medicine As it would be impracticable for the staff of the medical faculty to hold so many examinations he suggests that two different categories of examinations be introduced One group of subjects, including the most important ones should be passed by all the students the examinations in the second group being taken only by those who will be called according to an automatic scheme which will be unknown to the students so that they shall prepare themselves for all the examinations, not knowing whether they will be required to take them The examinations should be again divided throughout all the semesters of study and not crowded into the last semesters, as they now are This reform would allow the same time for medical studies as at present but a new bill regulating the practice of medicine, which is to be introduced into the parliament in the near future, will make it compulsory, for every doctor of medicine who desires to practice in the country to spend a year in one of the general hospitals of the country This virtually means that the medical studies will be prolonged by another year The proposition of Professor Hlava is being criticized, especially by the representatives of the clinical branches of medicine, as being too theoretical and as not allowing sufficient time for practical training, but his suggestion has aroused such an interest in the reform of

the study of medicine that, very probably, some changes will be made for the improvement of the medical curriculum, which has not been changed since 1903

Venereal Diseases Bill

The senate recently accepted the venereal diseases bill which was introduced by the cabinet It is somewhat surprising that the bill was accepted unanimously, as it was anticipated that there would be some opposition, at least from the Catholic party since the Catholic papers carried on a campaign against this bill, which introduces abolition in place of the present system of reglementation The minister of health Dr Boh Vrbensky, made a speech when presenting this bill to the parliament and it is said to be due to his eloquence that all opposition to the bill was suppressed and the bill accepted unanimously The bill will not appear before the house of commons before the fall season, and as no opposition to it is anticipated there, after such a splendid reception in the senate, it is probable that the bill will become a law late in the fall

Social Medicine Congress

A social medicine congress will be held in Munkac, June 4-7 Munkac is the capital of Ruthenia an autonomous territory within the boundaries of the Czechoslovak republic It is generally known as the most backward province of the republic in matters of hygiene The people of this territory have had very little education, and little was done to educate them in hygiene before the end of the war When the territory joined the Czechoslovak republic, a number of enthusiastic Czech physicians, headed by Dr A Albert, came to this neglected country and have worked ever since for the improvement of conditions Now that the most dangerous epidemic diseases have been controlled, the physicians of Ruthenia are calling their colleagues from the rest of the republic to come to Ruthenia for a congress of social medicine, and are asking the best advice for the development of a local program in social medicine As the congress is well prepared and unusual interest has been aroused, it promises to become a real milestone in the development of public health, not only for Ruthenia but also for the whole of Czechoslovakia

Tuberculosis Problems

The general meeting of the German Commission for the Campaign Against Tuberculosis was held in Bad Kosen in May In spite of the advantages that large cities offer to conventions, most congresses in Germany are now held in the smaller towns, for the reason that accommodations are procured more easily and more cheaply There is less competition in the way of outside attractions, hence, a better attendance is secured at the scientific meetings In recent years, the spas have become popular as meeting places for congresses The visitors become acquainted with the equipment of the watering place, and this serves as an excellent advertisement The scope of the tuberculosis congress did not measure up to the amplitude of last year's congress which was the first to be held since the opening of the war, hence, many problems growing out of the war were discussed At this year's congress, Kirchner's lecture on the part that human and bovine tubercle bacilli play in the origin of lupus awakened considerable interest Kirchner subjected particles of lupus-infected tissue to careful scrutiny and found that about half of the affections were traceable to bovine tubercle bacilli Welfare work among the tuberculous of the middle classes, who on account of special difficulties in supporting themselves, cannot help themselves to the same extent as formerly, but are obliged at times to accept assistance, was discussed at length In the course of the discussion, it was brought out that, at present, there are many more cases of tuberculosis in families of the middle class than formerly—many more than in working men's families Putter the director of the Berlin welfare center for the middle classes, vouchsafed the information that, among the 8 928 tuberculous patients receiving assistance, there were 1 654 officials, 119 professors, 153 teachers and 88 authors and artists

Scurvy in Berlin

At the last session of the Society for Internal Medicine two cases of scurvy that had developed in Berlin were presented It was in accord with the present-day conception that these cases had arisen owing to a lack of fresh vegetables and potatoes the result of the extraordinarily high prices demanded which put vegetables out of the reach of the poorer classes There seems to be also an actual scarcity of fresh vegetables one assigned reason for which is the large amount exported to foreign countries I am aware that this presents a view as to economic conditions, and especially food conditions prevailing in Germany differing from the one received from newspaper accounts which report observations of feasting in the high-priced restaurants of Berlin That such feasting is participated in mainly by foreigners, who, taking advantage of the favorable exchange rates, are living here on the fat of the land, or at most by some of Germany's newly rich, is a fact not brought out by the foreign press

Fixing of Medical Fees

Physicians in a city of Bavaria adapt the medical fees to the increased cost of living They base their fees on the prevailing price of bread They make this fact known by the following notice, posted in their waiting rooms

> The continual advance in the cost of living compels the physicians to adapt their fees to the sinking value of the mark Until further notice, *therefore the minimum fees will be based on the fees in vogue just preceding the war* (3 marks for a visit 2 marks for office consultation 1 mark for every 2 kilometers of distance traversed) and will be figured in the following manner The current price of a pound loaf of bread will be divided by 15 (in 1914, a pound loaf of bread cost 15 pfennigs) The resulting quotient will be used as a multiplier, and the prewar fees given above will be increased in exact proportion with the increase in the cost of bread

To illustrate The new bread price in Munich is 3 80 marks which is twenty-five times that of 1914 (15 pfennigs) Accordingly, the minimal medical fee for a domiciliary visit would be 75 marks, the office consultation fee, 50 marks, and the mileage allowance for every two kilometers traveled, 25 marks

---

Marriages

GEORGE EDWARD WEBB HARDY, Catonsville, Md, to Miss Minnie Gertrude Calary of Jarrettsville, Md, June 10

WILLARD STRICKLAND Wendell, N C to Miss Cleo Mariner of Pocomoke, Md, at Richmond, Va, May 10

EARL VINCENT MORROW to Miss Frances D Coakley, both of Portland, Ore, June 10, at Chehalis, Wash

ROBERT GRAHAM WIATT, University Va, to Miss Marian C Myers, Charlottesville, Va, May 5

SAMUEL GIBBS MILLIKEN to Miss Harriet Elizabeth Bain, both of Galveston Texas, June 24

JESSE LITTLETON MEEKS to Miss Ione Tumlin both of Gainesville, Ga June 1

KENNETH ROSS MCALPIN to Miss Margarethe Potter, both of New York, June 14

WINIFRED VIERS Minneapolis, to David T Wooster of San Jose, Calif, June 13

JOHN TERRELL SCOTT Lynchburg, Va, to Miss Vivian White of Denver June 14

Deaths

Edward Hall Nichols ⊕ Boston, Medical School of Harvard University, Boston, 1892, was taken ill after finishing an operation in a Brookline hospital and died, June 12, from cerebral hemorrhage, aged 58 He was assistant professor in surgical pathology and surgery, 1904-1913, and since 1916, clinical professor of surgery in his alma mater He was also director of the cancer laboratory of the Croft Research Fund, Boston During the World War, Dr Nichols first served as surgeon-in-chief to the first Harvard surgical unit with the British army in France in 1915 Following his return he joined the American Army and served as chief surgeon of U S Base Hospital No 7 in France with the rank of lieutenant-colonel, and was cited by General Pershing for exceptional meritorious and courageous conduct Dr Nichols was a member of the American Surgical Association, American Association of Pathology and Bacteriology, the Society of Clinical Surgery and several other societies

Joseph A Crook, Jackson Tenn , Jefferson Medical College, Philadelphia, 1870, member and former president of the Tennessee State Medical Association, and one of the organizers, and former president of the West Tennessee Medical Association, for thirty-four years a trustee of Union University, for thirty-five years district and division surgeon of the Illinois Central Railroad, died June 12, aged 74

Jacob Chris Lange, Pittsburgh, Pa , Bellevue Hospital Medical College, New York 1875, member of the Medical Society of the State of Pennsylvania, one of the founders and formerly dean and professor of principles of medicine and clinical medicine at the Western University of Pennsylvania, Pittsburgh, at one time president of the Allegheny County Medical Society , died, June 7 aged 67

Conrad William Wilkowske ⊕ Chippewa Falls, Wis , Homeopathic Medical Department of the University of Minnesota, Minneapolis, 1904, member of the Minnesota Academy of Ophthalmology and Oto-Laryngology , was drowned in Round Lake, June 17, aged 47, when the boat from which he was fishing overturned

William V Marmion, Washington D C , University of Pennsylvania School of Medicine, Philadelphia, 1866, served as surgeon in the U S Navy on the flagship *Monongahela* in 1866, in 1883 the degree of Master of Arts was conferred on him by Georgetown University , died, May 24, aged 82, following a long illness

Joseph A Gates ⊕ Kenyon, Minn , University of Minnesota College of Medicine and Surgery Minneapolis, 1895, served in the M C, U S Army, during the World War, with rank of captain, was instantly killed, June 15, aged 52, when the automobile in which he was driving was struck by a train

Charles Bernard Burke, Atlantic, Iowa , Northwestern University Medical School, Chicago, 1906, member of the Iowa State Medical Society , served in the M C, U S Army, during the World War, with rank of captain, was found dead in his office, June 19, aged 42 from cerebral hemorrhage

Hartwell Carver Howard, Champaign, Ill , Starling Medical College, Columbus, 1850, former president of the Champaign Medical Society , member of the city council and board of education, at one time president of the board of trade, died, June 5, aged 92

George A Coors, Memphis, Tenn , University of Arkansas Medical Department, Little Rock, Ark , 1888, Chicago Homeopathic Medical College, 1892, died May 12, at a hospital in Rawlins, Wyo , aged 53 from chronic nephritis and uremia

Joseph Edward Kane, Portland, Ore , University of Oregon Medical School, Portland, 1907, member of the Oregon State Medical Association, on the staff of the St Vincent's Hospital , died, June 8, aged 39, from influenza and pneumonia

Walter C Hemingway, Hemingway, S C , Medical College of the State of South Carolina, Charleston, 1900, died, June 3, aged 45, from burns received in the explosion of a gasoline tank when he was sterilizing some instruments

Ewell Pollett, Jonesboro, Ark , University of Tennessee College of Medicine Memphis 1916, member of the Arkansas Medical Society , was instantly killed, June 16, aged 33, when the automobile in which he was driving overturned

John Wilson Wood, Lindsay, Ont , Victoria University Medical Department, Toronto Canada, 1869, member of the board of education, formerly mayor of Lindsay , at one time warden of Victoria County , died, March 2

Franklin P Gates, Manteo, N C , Bellevue Hospital Medical College, New York, 1886, member of the Medical Society of the State of North Carolina, died, May 20, at Norfolk, Va aged 62, from valvular heart disease

George M Glaser ⊕ Chicago, Rush Medical College Chicago, 1892, practitioner in Chicago for nearly thirty years died June 26, at St Luke's Hospital, aged 53, from spinal meningitis, following an operation

Clarence Warfield ⊕ Baltimore, Baltimore Medical College Baltimore, 1891, member of the American Academy of Ophthalmology and Oto-Laryngology , died, May 10, aged 56, from pulmonary tuberculosis

Joseph Richard Culkin ⊕ Rochester N Y , Bellevue Hospital Medical College, New York, 1887, on the staff of the St Mary's Hospital , member of the board of health, died suddenly, June 9, aged 55

Henry Thomas Rooney, San Francisco, Cooper Medical College San Francisco, 1902 member of the Medical Society of the State of California , died, June 3 aged 45, from angina pectoris and myocarditis

Robert Burns Harriman, Worcester, Mass , University of Vermont College of Medicine Burlington, Vt , 1903, on the staff of the Worcester State Hospital , died, June 6, aged 45, from pneumonia

Moses Cline Hughey, Marianna, Ark , Memphis Hospital Medical College Memphis, 1903, member of the Arkansas Medical Society died, May 28, aged 44, at Hot Springs, from uremia

Frederick Rovitti, New York, Medico-Chirurgical College of Philadelphia 1914, served during the World War in the M C U S Army died, June 13, at Wilmington, Del , aged 30

Paul Boyton Doyle, Pittsburgh, Western Pennsylvania Medical College Pittsburgh 1897, member of the Medical Society of the State of Pennsylvania , died, June 6, aged 47

Jesse D Dickinson, Galva Ill Hahnemann Medical College and Hospital of Chicago, 1874, died, June 10, aged 75, at the Galesburg Cottage Hospital, following an operation

Edwin Owen Woods ⊕ Chicago, Rush Medical College Chicago, 1912 assistant surgeon U S Public Health Service, formerly stationed at Manila P I , died, June 26, aged 37

Ambrose William Jones ⊕ Owingsville Ky , Kentucky School of Medicine Louisville, 1890, died, June 8, aged 51, at the Good Samaritan Hospital following an operation

Andrew Jackson L Dennis, Montgomery, Ala , Southern Medical College, Atlanta, Ga , 1890, member of the Medical Association of Alabama , died, April 12, aged 66

Frederick D Sowden, Philadelphia, Jefferson Medical College Philadelphia, 1883, member of the Medical Society of the State of Pennsylvania , died, June 6 aged 50

Herman Amos Jergesen, Tulsa, Okla , Wisconsin College of Physicians and Surgeons Milwaukee, 1912, was shot and instantly killed by his wife, May 25, aged 38

Albert Lauder Kinsey, Gravenhurst, Ont , University of Toronto Faculty of Medicine Toronto Canada, 1908, died April 29, aged 37, following a long illness

Clarence Lloyd McNett, Towanda, Ill , College of Physicians and Surgeons, Chicago, 1903, was killed, June 21, in an automobile accident, aged 43

Joseph C Cleveland ⊕ Bald Knob, Ark , Missouri Medical College, St Louis, 1888, served as mayor of Bald Knob for ten terms , died, June 4, aged 69

Corydon Eugene Rogers, Seattle, Medical Department of the University of the City of New York, 1868, Civil War veteran , died, May 29, aged 79

Nils Albin Killberg ⊕ Chicago Hahnemann Medical College and Hospital of Chicago, 1918, died, June 20, aged 33, from septic pneumonia

Rudolph Meyer ⊕ Chicago Bennett College of Eclectic Medicine and Surgery Chicago, 1903, died, April 14, aged 43 from paresis

John W Mebane, Paris Ky Meharry Medical College, Nashville, 1894, died, June 11, aged 56, from septicemia

John Frederick Baker, Davenport, Iowa , Bellevue Hospital Medical College, New York, 1868, died, June 16, aged 76

Clara Augusta Williams, Boston (years of practice), died, April 14, aged 73, from heart disease

⊕ Indicates Fellow of the American Medical Association

The Propaganda for Reform

IN THIS DEPARTMENT APPEAR REPORTS OF THE JOURNAL'S BUREAU OF INVESTIGATION OF THE COUNCIL ON PHARMACY AND CHEMISTRY AND OF THE ASSOCIATION LABORATORY TOGETHER WITH OTHER GENERAL MATERIAL OF AN INFORMATIVE NATURE

"MEDICAL" TESTIMONIALS FOR CHIROPRACTIC

Opinions of Some Alleged Well-Known Medical Men on Chiropractic

Chiropractors affect with 'patent medicine' fakers, a fine disdain for scientific medicine and the medical practitioner How readily, however, do both seize with avidity on any statement made by an individual who may be presumed to have the right to put 'M D" after his name—provided that statement seems favorable to the cause, or may be so twisted as to make the public believe that a reputable physician has spoken a good word, either for chiropractic or the nostrum industry

For some time there has been going the rounds a chiropractic advertisement purporting to quote "Opinions of Well Known Medical Men" on chiropractic The material obviously emanates from one of the chiropractic 'ad" factories These make a business of supplying the individual chiropractor with advertising copy that he because of his educational deficiencies, would be unable to write for himself Realizing that a chiropractic diploma may be obtained even by those who never reached the eighth grade of the secondary schools, these chiropractic advertisement factories doubtless, meet a need of the trade.

According to these stock advertisements

> " there is an ever increasing number of M D's all over the United States and Canada who understand, appreciate and practice straight Chiropractic to the exclusion of medicine and every other method, as witness the following selected at random

Then follow what purport to be quotations from physicians For a while these advertisements contained a quotation credited to Dr Charles Mayo and reading "The drugless healer is one of the best things that has come into the life of the present" Of course, Dr Mayo never made such a statement or anything resembling it, but the reiteration of the falsehood was such that he found it necessary to publicly deny, through the pages of THE JOURNAL, the preposterous canard The advertisements also contained an alleged quotation from Dr Richard Cabot. Whether Dr Cabot ever made the statement or not is immaterial, as by no stretch of the imagination can it be twisted into an endorsement of chiropractic Sandwiched in, however, between a number of blatant testimonials for chiropractic, it, doubtless, serves the purpose intended

The rest of the testimonials credited to alleged physicians will be given in detail and following the quotation a brief statement of what was found regarding the individuals quoted. It is to be borne in mind that the biographical data on file in the American Medical Association's offices are based on official information and have been checked and rechecked It may, therefore be assumed that the information is as accurate as can humanly be expected While the quotations in the advertisements are not arranged in alphabetical order, we will present them in that sequence for the purpose of more ready reference

LEE W EDWARDS M D Omaha — Chiropractic truth is so simple so mathematically exact that it seems too good to be true

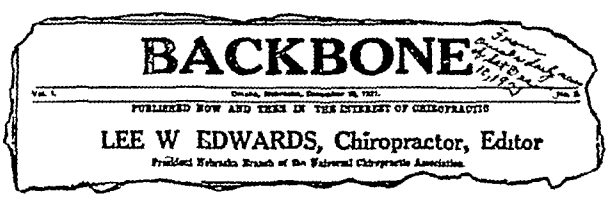
According to our records Lee W Edwards was born in 1870, was graduated in 1893 by the University of Nebraska, College of Medicine He was licensed to practice medicine in Nebraska in 1894 and also holds a license in Wyoming His name appears in the Propaganda files as one of a committee protesting against compulsory vaccination His name also appears as the "state vice-president' of the "American Medical Liberty League" an organization of "drugless healers and 'patent medicine" makers We have, too, a quarter page advertisement in our files from the *Western Medical Review* of June 1920, in which Edwards holds himself out as a chiropractor and solicits "spinal X-Ray work"

R C ELLSWORTH M D Astoria Oregon —"If I were confined wholly to one branch of therapeutics I would choose Chiropractic unhesitatingly I hesitate to state the number of women I have helped to health and the evasion of the surgeon's knife thru Chiropractic adjustments alone

In some of the advertisements the initials of this person are given as R E We have no record of any man of the name of R C Ellsworth or R E Ellsworth ever holding the title of 'M D or being licensed to practice medicine

E W FEIGE M D Huron S D —"There are many Chiropractors who in certain kinds of cases I am convinced, do vastly more good than the most highly educated physician

This man according to our records was born in St Joseph, Mo in 1871 was graduated in 1895 by the Chicago Homeopathic Medical College The records also indicate that Feige was one of the incorporators of a preposterous organization calling itself the "Association of Independent Doctors" which was brought into existence, according to its creator, "to combat the Medical Trust"—meaning the American Medical Association Feige's name also appears as a member of the "staff (Heaven save the mark!) in 1910 of the "Weltmer Institute of Suggestive Therapeutics" At that time the following letters appeared as a suffix to Feige's name "M.D D O Oph D, D C" Whether Feige has accumulated any more nomenclatorial appendages during the past twelve years, we do not know



BACKBONE

PUBLISHED NOW AND THEN IN THE INTEREST OF CHIROPRACTIC

LEE W EDWARDS, Chiropractor, Editor

Reproduction (reduced) of an advertisement in an Omaha newspaper Evidently L W Edwards is featured as a physician only when it suits chiropractic needs

JOH A. FISHER M D Philadelphia —"The Chiropractors are working marvels so wonderful that even members of the medical fraternity are taking notice of their great work.

This man apparently, spells his name both "Fisher" and 'Fischer and the latest Philadelphia telephone directory has him classified both under "Chiropractors' and under "Physicians Fischer according to our records, was born in 1872 and was graduated in 1895 by the Hahnemann Medical College and Hospital of Philadelphia Needless to say, Fischer is not a member of his local medical society but, according to the latest issue of the Philadelphia telephone directory he is a member of the "Philadelphia County Chiropractors Association

FRED L FISCHER M D D C Philadelphia Pa — 'In the acute cases one gets marvelous results Do not be afraid of such cases In adjustments you have absolute control and after a little experience you will soon realize you have an unequaled health system in your hands I am in better shape to say that because I have gone through every stage of mixing until today I am an out and out Chiropractor

The records fail to show that any man of this name has any right to call himself M D ' or has ever been licensed to practice medicine neither does the latest Philadelphia telephone directory show any man in the city of Philadelphia of this name, chiropractor or otherwise

A A GREGORY M D — Under spinal adjustments acute diseases are cut short and aborted and chronic diseases recover which have been believed to be incurable.

This presumably refers to Alva E Gregory, not "A A Gregory" This man according to the records, was graduated in 1897 (when he was thirty-six years old) by the University of Texas Medical Department. A few years ago

Gregory was editor of the *Progressive Physician* which carried advertisements of various chiropractic institutions and also announced 'To the Progressive Physicians of America" the fact that Alva E Gregory was giving post-graduate courses" in "Chiropractic Spondylotherapy" The publication also carried advertisements of the "Gregory Office Supply Company," Alva Emery Gregory, secretary This company sold "Gregory's Motor Traction Table" which would "remove the infirmities of old age, cause the paralyzed to walk" and "restore health and vigor of youth" In addition to being editor of the *Progressive Physician* and secretary of the Gregory Office Supply Company, Alva Emery Gregory seems to have been President of the "Palmer-Gregory Chiropractic College" of Oklahoma City A "well known medical man," indeed!

H G GOULD M D Nephi Utah — I have been keeping my eyes open and observing cases under Chiropractic adjustments I am convinced of the superior merit of this form of health practice

According to the records, this man, now in Spokane, Wash, was graduated in 1884 by the Fort Wayne (Ind) College of Medicine, now defunct Gould's name appeared in the medical directories from 1886 to 1900 at Medicine Lodge, Kansas, and St Louis, Mo It does not appear again until 1918, when it is found under McKinney Texas In the same letter from which the quotation given above appears, Gould tells why he 'abandoned medicine" In this letter we read I have seen a beautiful girl of eighteen years die with all the symptoms of morphine poisoning after I had given her as medicine ⅛ grain of morphin sulf I have known ¼ gram of calomel, which I gave as medicine, to cause every tooth to drop from my patient's head"

F A HALL M D D C Indianapolis — When Chiropractic was brought to my attention I listened to seemingly extravagant statements relative to it and I was offended because it reflected odium on the old time honored profession in which I no longer sincerely believe In time it dawned on me however that Chiropractic patients who had from a medical standpoint been considered hopeless cases such as those with rheumatism diabetes Bright's disease infantile paralysis and many other maladies were getting well so that I began to read up on Chiropractic The more I read about it the more I saw it to be the means of true salvation from the curse of disease

The records fail to show that this man is entitled to write M D" after his name or has any license to practice medicine The Indianapolis telephone directory classifies Hall as a chiropractor" only Hall carries a display advertisement

Reproduced in miniature from the Indianapolis telephone directory Here too the M D becomes D C when seeking business

(reproduced in miniature) spread the width of the page in his local telephone directory and claims therein to have been Formerly a Medical Doctor and Pharmacist '

D T KRUDOP M D — Clinical records show that there is hardly a recognized germ of disease that cannot be successfully treated by Chiropractic adjustments

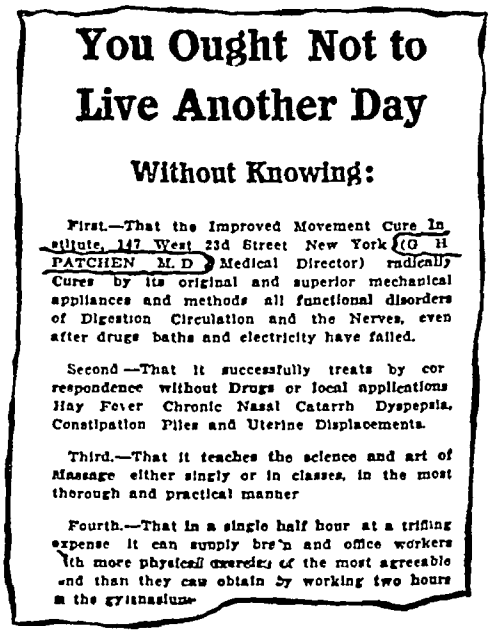
This man was graduated by the Hahnemann Medical College in 1888 He died in January, 1917 His testimonial is still going strong

G H PATCHEN M D, New York — Chiropractic removes the cause of disease more promptly radically and permanently than any other known method

This man, according to the records, was born in 1845 and was graduated in 1886 by the New York Homeopathic Medical College Patchen was for some years advertised as the Medical Director' of the "Improved Movement Cure Institute" which, according to the advertisements, "Radically cures, by its original and superior mechanical appliances and methods, all functional disorders of digestion, circulation and the nerves, even after drugs, baths and electricity have failed" The Institute also "successfully treats by correspondence" uterine displacements and various other conditions! In the April, 1922, issue of the official organ of the egregious "Allied Medical Associations of America," we find Patchen given as "Chairman" of the section on "Drugless Therapy" and also as "Chairman" of the section on "Irodology"—whatever this may be

E G RUTHERFORD, M D Birmingham Ala — 'Chiropractors are obtaining results that I could not have obtained with medicine or surgery

Rutherford, according to the records, was graduated by the University of Alabama School of Medicine in 1909—when he was thirty-eight years old We have in our files an advertisement of Rutherford's in which he tells of his conversion



You Ought Not to Live Another Day

Without Knowing:

First.—That the Improved Movement Cure Institute, 147 West 23d Street New York (G H PATCHEN M D Medical Director) radically Cures by its original and superior mechanical appliances and methods all functional disorders of Digestion Circulation and the Nerves, even after drugs baths and electricity have failed.

Second.—That it successfully treats by correspondence without Drugs or local applications Hay Fever Chronic Nasal Catarrh Dyspepsia, Constipation Piles and Uterine Displacements.

Third.—That it teaches the science and art of Massage either singly or in classes, in the most thorough and practical manner

Fourth.—That in a single half hour at a trifling expense it can supply brain and office workers with more physical exercise of the most agreeable and than they can obtain by working two hours in the gymnasium.

One of the advertisements of the Improved Movement Cure Institute of which G H Patchen was Medical Director

from medicine to chiropractic and states that he had associated with him a chiropractor who, says Rutherford, is 'giving adjustments and obtaining results that I could not have obtained with medicine or surgery" Rutherford's name appears in the Birmingham telephone directory classified as a chiropractor," and not as a physician

WM A SEELEY M D D C —' Results are what count and Chiropractic adjustments when scientifically given bring them notwithstanding what our medical friends (?) may say to the contrary '

The records show that William A Seeley was born in 1847 and was licensed to practice medicine (Homeopathy) in Iowa many years ago on the basis of 'years of practice" There is nothing to show that Seeley was ever graduated in medicine Seeley admitted in a letter to a chiropractic concern that he had practiced medicine twenty years, osteopathy four years and chiropractic seventeen years Seeley died in February, 1918, his testimonial still lives

JOHN M SHALLER M D Cincinnati — Many chiropractors are adjusting from ten to fifty patients a day to the satisfaction of the majority of their patients Most of these patients are chronics who made the rounds of the various kinds of treatment, both regular and irregular The results would astonish any medical man who would make an investigation '

John M Shaller, according to the records was born in 1856 and was graduated in 1874 by the Cincinnati College of Medicine and Surgery, which went out of existence twenty years ago Shaller is the author of a pamphlet, published in 1917, entitled "Cramps in the Feet Caused by Vertebral Subluxations"

W H SHUMLEY M D — Eighty per cent of the population are afflicted with some form of spinal defect that is the cause of so much nervousness, indigestion headache rheumatism mental weakness and other grave and dangerous diseases

In some of the advertisements this name is given as "W H Schumpley, M D," but in none of the advertisements is

an address given We have no record of any individual of either name having been graduated in medicine or licensed to practice

W W YORK M D City Point Va —"I am convinced of the superior method of the Chiropractic form of health practice"

The records fail to show any man of this name as a graduate in medicine or licensed to practice medicine

ALFRED WALTON M D, Philadelphia — Chiropractic reaches successfully a larger number of so called chronic diseases and is so much superior to the drug method that it is truly laughable to compare them"

This man was graduated by the Harvard University Medical School in 1879 In 1880 he was practicing in New York City as a physician and at the same time manufacturing and selling "Walton's Oxygen For Consumption Pneumonia, Anemia, etc" Between 1914 and 1917 Walton moved to Philadelphia where he began practicing as a chiropractor He had no license to practice medicine in that state but was licensed to practice drugless therapy Walton's testimonial is still doing service although Walton himself died in February, 1920

Correspondence

FAILURE OF DIAGNOSIS OF MASTOIDITIS

To the Editor —Drs Isidore Friesner and Wendell C Phillips (THE JOURNAL, June 10), in reporting five cases of mastoiditis with atypical symptoms, conclude that textbooks and teachers have failed to describe this condition adequately to students I feel that the average medical student in the best schools is not only not taught to diagnose atypical mastoiditis but also is not taught to diagnose any mastoiditis

A physician of good reputation as to ability recently solemnly assured me that a patient did not have mastoiditis because no postauricular edema was present, and as to any of the other textbook signs, he did not know whether they were present or not After I had been in general practice for some years and had done a fair amount of major surgery I saw a child with a moderate rise of temperature and a pain in the ear The tympanum ruptured spontaneously the next day, and the discharge was profuse In my blissful ignorance I told the mother that all was now well, and that the child would be well soon, but the child died in a few days from meningitis

Recently the case of a child aged 4 years who had had a chronically discharging ear for the past two years, was brought to my attention Three days before I saw the child the discharge ceased rather suddenly, the child began to cry and put the hand to the side of the head, the temperature began to go up, and the child developed a facial paralysis on that side A regularly qualified physician was called who told the parents that there was nothing seriously wrong and that the child would be all right in a few days Three days later another physician was called In addition to the previous symptoms the child now showed postauricular edema, a temperature of 102, pulse 140 and respiration 44 The child was sent immediately to the Presque Isle General Hospital, where I saw her first The child arrived in a semistuporous condition I operated on the child at once There was a subperiosteal abscess, a mastoid full of foul smelling pus under a good deal of tension, and a moderate sized perisinuous abscess In spite of an immediate operation, a radical opening of the sinus and resection of the jugular the child went from bad to worse and died in two days with symptoms of septic pneumonia

In the smaller cities and towns the condition described will more frequently come first under the observation of the general practitioner rather than under that of the otologist It is usually on the general practitioner that the burden of the early diagnosis of this condition falls From my own experience and the evidence about me I feel that the great majority of medical students do not receive proper and sufficient instruction on this subject

J L JOHNSON, M D, Presque Isle, Maine

"PERFORATING ULCERS OF THE CECUM"

To the Editor —In THE JOURNAL, June 10, 1922, p 1792, Dr G K Dickinson reported three cases of perforating ulcers of the cecum No very satisfactory explanation of this condition was advanced, although it was suggested that one case was due to 'hemorrhagic cecitis" and the others to "a primary inflammation of the adenoid tissue" of the cecum Emphasis was placed both in the article and in the discussion on the possible primary role of bacterial infection

After a careful perusal of the three reported case histories, may I suggest that Dr Dickinson may have been dealing with instances of acute, subacute or chronic obstruction of the large intestine at some point far distal to the cecum What the exact cause of the ileus may have been is immaterial, but it is known that colonic obstruction of any kind is not infrequently associated with ulceration and even perforation at points proximal to the site of the primary condition, and that a favorite location for such a secondary pathologic condition is in the cecum These so-called Dehnungsgeschwure' (distention ulcers) were described some time ago by Kocher They have no special relation to the lymph follicles They may be single or multiple, they may vary in size from a pin point to a large rent, and they may be round or irregular, with punched out or undermined edges Detailed studies on this subject are those of von Greverz (*Deutsch Ztschr f Chir* **77** 57, 1905) and of Shimodaira (*Mitt a d Grenzgeb d Med u Chir* **22** 229, 1910) and a brief but satisfactory account is available in the second (1921) edition of Schmidt-von Noorden's Klinik der Darmkrankheiten pp 631-632 Bacterial invasion plays only a secondary role in this phenomenon

The object of this communication, however, is not so much to suggest a more satisfactory explanation of the ulcers in question as it is to stress the general proposition that, in any form of distal colon obstruction, right colon stasis and right colon symptoms may be predominant, and unless the physician is on his guard a diagnosis of "some form of appendicitis is made—as it was made in each of the three cases reported When the clinical picture is not acute and only a *mild chronic or recurrent* obstructive condition is present in the distal colon a diagnosis of "chronic appendicitis" is almost invariably accepted unless careful consideration is given to the possibility mentioned above

This possibility is unfortunately not generally accorded the recognition it merits, and I therefore discussed it at some length in a recent paper (On Five Common Clinical Types of Appendicitis, *M Clinics North America* **5** 1081 [Jan] 1922) under the head of Type III of the classification therein presented Patients suffering from this type of so-called appendicitis may complain of intermittent or constant pains along the course of the colon, very commonly in the right lower quadrant, and not infrequently associated with palpable cecal erections Careful study and the judicious employment of special diagnostic methods such as the roentgen ray, will bring out a clinical picture that strikingly resembles in miniature that of obstructing distal colon carcinoma for example with the difference that in the case under discussion we are dealing with long-standing, benign factors such as spastic constipation, redundancy of the splenic or pelvic colon with or without recurrent incomplete volvulus some forms of

colitis, and anorectal conditions such as dyschezia and spasm, whether idiopathic or secondary to local disease (fissure, ulcer, hemorrhoids) Any such obstruction to the fecal column, particularly when the effect is intermittent or recurrent, tends to throw back the contents to the head of the colon (exaggerated antiperistalsis), and thus brings on the usual sequence of hypertrophy and dilatation, with local irritation and subjective discomfort

It is much to be desired that a wider recognition of this really common syndrome will lead to correct diagnosis and appropriate treatment, and so prevent not only the possible terminal stage of 'perforating ulcers of the cecum," but also the injudicious and unhelpful removal of innumerable "chronically diseased appendixes" that do not exist in reality

JOHN L KANTOR, M D, New York

THE CASE OF WILLETTA HUGGINS

To the Editor —I have no quarrel with Professor Jastrow, as I am neither a psychologist nor an oculist, but I presided at the meeting of the Chicago Medical Society when the case of Willetta Huggins was presented, and I believe that, in justice to the intelligence of the audience, those who read his article in THE JOURNAL of June 17 should know how the sight test was applied before the Chicago Medical Society

A pair of ordinary dust goggles was used, and over each glass was placed a piece of dark paper, and then a heavy pad of cotton I placed these over my own eyes first, and then over the eyes of Miss Huggins

If this young lady read with a slit of vision as Professor Jastrow states when she performed the tests before our members, it is even more marvelous than his theory of the will to believe"

J S NAGEL M D Chicago
President, Chicago Medical Society

MEDICAL TERMINOLOGY IN GERMANY

To the Editor —Peculiar results of the European war continue to crop up in unexpected—or at least unforeseen—places, from time to time This is true not only in politics geography and finance, but in art and science as well In 1920, the Vereinigung der deutschen medizinischen Fachpresse designated a commission to collaborate with the Deutsche Gesellschaft fur innere Medizin in selecting German terms which might replace French and English expressions that have been so long in use in medical literature as to have become in many instances a part of the medical language of all nations The *Deutsche medizinische Wochenschrift* (48 493, 1922), the *Munchener medizinische Wochenschrift* (69 454, 1922) and other medical periodicals from Germany report the results of this collaboration and give the list of the French and English phrases to be interdicted and their German equivalents Of these new terms, many successfully convey their exact meaning at a glance, others require a little thoughtful investigation, while still others are composed etymologically of elements so nontechnical that their medical meaning is not easily arrived at—unless, perhaps, by a person "born in (the) two languages"—French and German or English and German Taking into account German unity and the German habit of discipline, we may assure ourselves that this terminology will secure instantaneous and universal adoption at the hands of writers on professional themes in Germany, and that such old friends as "contrecoup" and "tic douloureux" will disappear henceforth from German medical literature It thus becomes important that those who avail themselves of the German periodicals—and especially those engaged in bibliography and the work of classification—should have at hand the list (which is appended) of the new German expressions and their older French and English equivalents

New Terms	Former Terms
Abwehrspannung	*defense musculaire*
ausserer Harnrohrenschnitt	boutonniere
Alopecia atrophicans	alopecie atrophiante
Binnenverletzung(des Kniegelenks)	derangement interne
Docht	*meche*
Drehtick	tic rotatoire
Einkerbung (des Bruchringes)	debridement
Florentiner Seide	fil de Florence
Gegenstoss	contrecoup
gemischter Schanker	chancre mixte
Gerausch des gesprungenen Topfes	bruit de pot fele
Geschlechtsverwechslung	erreur de sexe
gewaltsame Entbindung	accouchement force
gewaltsame Richtigstellung	redressement force
gewaltsames Beweglichmachen	brisement force
Glanzhaut	glossy skin
gleichsinnige Abweichung	deviation conjuguee
Herzbuckel	voussure
kleiner epileptischer Anfall	petit mal
Klopfbehandlung Beklopfung	tapotement
knotige parenchymatose Hepatitis	hepatite parenchymateuse nodulaire
Kolbenfinger	*osteoarthropathie hypertrophiante pneumatique*
Kreisbogenstellung	arc du cercle
Larva migrans	creeping disease
Malum perforans	mal perforant
Massen (reposition)	en masse
moralischer Schwach sinn	moral insanity
Mückensehen	mouches volantes
Muskeltick	tic convulsif
Nachblassen der Haut	dermographie blanche
Panzerkrebs	cancer en cuirasse
Peyersche Haufen	Peyersche plaques
Pulsdruck	amplitude
Pulshohe	altitude
Ruckansteckung	choc en retour
Rucklaufkatheter	catheter a double courant
Schleimhautpapeln	plaques muqueuses
Schmerztick	tic douloureux
Schwirren	fremissement
Sclerosis redux	chancre redux
Syphilis ohne Primaraffekt	syphilis d emblee
Tickkrankheit	maladies des tics
unausgepragte Basedowkrankheit	Basedow fruste
unausgepragte Formen	*formes frustes*
unbewusst erworbene Syphilis	syphilis ignorée
Syphilis insontium	
Vergleichsfarbe	teinte
Wandertrieb	Fugue-Zustande

[COMMENT—It remains to be seen whether language can be created by edict in the new Germany —ED]

"MEDICAL EDUCATION"

To the Editor —I have just read (THE JOURNAL, June 3 p 1743) certain reflections of a student relative to medical education Now for some suggestions anent that topic from the practitioner s standpoint

In my humble opinion (M D, Columbia, 1904) too much study is required of a purely theoretical nature The subjects of physiologic chemistry, materia medica, comparative anatomy etc, while extremely interesting have too many hours of the course devoted to them Would it not be wiser to focus on twenty drugs and have a broad, indelible knowledge of these, rather than ramble along over all the pharmacopeia? One should learn twenty drugs thoroughly and well, and read up the other 999 as parallel

What does the young graduate know of such topics as distribution of physicians in the United States, office equipment —how many rooms, where best to locate in a city or town, a roentgen-ray room, laboratory, bill collecting, how to go about it, how to collect difficult bills, office nurse, relation-

ship to hospitals, group practice clinics, insurance needs, protective accident, etc., with good safe companies, income tax laws, private sanatoriums and hospitals their outlook from a commercial and professional standpoint, connecting up with industrial work how to arrive, safe investments for the busy physician and the difference between stocks and bonds and oil wells?

I could fill a page with practical matters that are sure to be encountered by the young graduate immediately on emerging from school or hospital to practice—matters vital to his success and progress—yet matters which are not even mentioned by the school that is supposed to equip him for his business The gist of this protest is that the practical commercial material side of the practice is just about wholly neglected in our schools By hard knocks, costly errors and humiliations galore the aspiring medico learns in the hard field of life what he could have at least glimpsed somewhat in a much handier, less expensive shape in his good old alma mater

A commercial salesman or business man nowadays is not sent out to deal with the public until he is thoroughly schooled from every conceivable angle—he is even taught psychology His deportment, his dress his method of approach as well as his goods are studied with anxious care His corporation sees to that When will our medical schools create a business branch of the teaching—that limb from which depends the bread and butter?

Queries and Minor Notes

ANONYMOUS COMMUNICATIONS and queries on postal cards will not be noticed. Every letter must contain the writer's name and address but these will be omitted on request

DIGALEN

To the Editor —I am writing for information concerning the drug Digalen about which I believe the Council on Pharmacy and Chemistry has made a ruling The drug is in common use in this hospital though I have never ordered it and I believe that definite information concerning its action or lack of action together with accurate data would be of interest GEORGE FOSTER HERBER M D New York

To the Editor —I have had considerable occasion this winter to use the digitalis preparation called Digalen sold by the Hoffman La Roche Chemical Works and made in Switzerland I have seen very fine results from its use especially in pneumonia and I and other men here are anxious to have your report on it provided you have gone over it in the class of New and Nonofficial Remedies Your answer to this will be sincerely appreciated by myself and other local men

L H NOWACK M D Watertown Wis

ANSWER.—Digalen was introduced with the claim that it was soluble amorphous digitoxin (a substance unknown to chemists) and with the claim that it possesses all the advantages and none of the disadvantages of digitoxin such as cumulative effects and the production of nausea (claims which have been made for many proprietary digitalis preparations but always proved untenable)

In 1909, the Council on Pharmacy and Chemistry admitted digalen to New and Nonofficial Remedies after the manufacturer had discontinued the palpably unwarranted claims which had been made for the preparation The Council did not determine whether digalen contained soluble amorphous digitoxin' but accepted it merely as a standardized and fairly stable digitalis preparation In 1910 (THE JOURNAL Jan 1 1910, p 35) Hale reported that a review of the literature contradicted the claims made for digalen that digalen deteriorated with age, that it was relatively much less potent than corresponding amounts of crystalline digitoxin and that it was of about the same activity as digitalein As a result of Hale's report the Council in 1912 revised the New and Nonofficial Remedies description by omission of the statement that it is a fairly stable digitalis preparation A biologic study made at the University of Cambridge in 1912 (THE JOURNAL, Dec 7 1912, p 2074) indicated that digalen is not superior to an active tincture of digitalis

In 1913, Hatcher and Eggleston (THE JOURNAL Feb 15 1913 p 499) demonstrated that digalen was not devoid of the emetic action of digitalis preparations They reported that the relatively high emetic action of digalen was unmistakable while its action on the heart was less than claimed Hatcher and Eggleston (THE JOURNAL July 19, 1913, p 202) also found digalen very variable in strength, perhaps because of its low alcohol content

In view of increased extravagance of the claims for digalen the Council in 1915 made a reexamination of this product The Council concluded that the presence of amorphous digitoxin in digalen had not been established that digalen was variable in composition and action and that it produced the same gastric disturbances as other digitalis preparations The manufacturer offered to hold the claimed presence of amorphous digitoxin in abeyance but insisted on the claim that digalen was uniform in action and that it did not produce gastric disturbance In view of the insistence on these disproved claims the Council omitted digalen from New and Nonofficial Remedies (THE JOURNAL Sept 5 1914 p 881)

There is no available evidence to indicate that digalen has any advantage over tincture of digitalis or the infusion of digitalis for oral administration, and there is no evidence that it is equal to ouabain or strophanthin for intramuscular or intravenous injection With a better knowledge of proper dosage—as advocated for instance, by Eggleston (THE JOURNAL March 13 1920, p 733)—an increasing number of practitioners find that except in exceptional cases the desired action of digitalis may be obtained by the administration of the official tincture of digitalis

COLLOID BATHS IN TREATMENT OF DERMATITIS EXFOLIATIVA

To the Editor —Please describe what is meant by colloid baths as used in the treatment of dermatitis exfoliativa occurring after the administration of arsphenamin I have seen several references in which colloid baths were recommended but have no description of this special point in treatment Please omit my name —— W Va

ANSWER.—Colloid baths as used in the treatment of dermatitis exfoliativa are baths containing bran starch gelatin or similar substances A suitable colloid bath can be thus prepared Two cups of oatmeal are added to 2 quarts (liters) of water and boiled The boiled oatmeal is then placed in a bag and the bag hung in a bathtub of water at a temperature of 100 F One cup of sodium bicarbonate is then added The bath is employed for twenty minutes three times a day Lassar's paste without salicylic acid, or any other bland salve may be used in the intervals between baths

PREPARATION OF FERRI HYDROXIDUM CUM MAGNESII OXIDO

To the Editor —This being the season when much arsenic is being used on potatoes and garden truck I want to obtain a definite formula for preparing the antidote (ferri hydroxidum cum magnesii oxido) The United States Pharmacopeia and your Epitome of the U S Pharmacopeia and other works say to take 10 fluidrams of solution of ferric sulphate Does this mean a saturated solution? If not how much ferric sulphate should be used? Should the final mixture of the iron and magnesia be greenish? G C MOOREHEAD M D Idagrove Iowa

ANSWER.—The directions of the U S Pharmacopeia for the preparation of ferri hydroxidum cum magnesii oxido are most explicit and easily followed The iron solution used in the preparation of the arsenic antidote is the pharmacopeial solution of ferric sulphate Since a ferric solution is used the precipitate which is produced when the ingredients are mixed has the reddish-brown color of ferric hydroxid The greenish color to which our correspondent refers would be obtained if a solution of ferrous sulphate had been used

---

Leprosy in Japan.—According to police reports there are 16,261 lepers in Japan which is lower than the actual numbers since the police report only advanced cases There are five government leper hospitals in Japan the largest of which is located in Maruyama-Mura near Tokyo Only voluntary cases in more or less advanced stages are taken in these hospitals as there is no compulsory segregation

LAY COMMENT ON ALCOHOL RESOLUTION

The resolution on the alcohol question adopted by the House of Delegates of the American Medical Association at the recent annual session in St Louis was widely commented on by the lay press The New York *World* says that the vote of the House of Delegates is interesting as an exhibit of professional opinion, but points out that "Congress is its own medical authority, just as it is its own economic and financial authority It has ordered, in effect, that whisky is not necessary in medical practice and, having rejected the testimony of the doctors as incompetent, it is immaterial how large a percentage of practicing physicians regard the use of whisky as beneficial" Heading its editorial sarcastically, "A Petition to Old Dr Congress," the *World* suggests that the American Medical Association would have more hope of securing relief from the Volstead regulation if it based its plea on practical politics instead of on scientific therapeutics

The Brooklyn *Eagle* points out that it is axiomatic that humanity suffers unless physicians secure freedom in alcoholic prescriptions and pure liquor for their patients, and the Brooklyn *Citizen* affirms that the action taken indicates that "the influence of the medical profession may now safely be said to be decisively arrayed on the side of a liberal modification of the Volstead Act"

The Paterson N Y, *Chronicle* believes that the questionnaire conducted by THE JOURNAL indicating that physicians in the cities believe that alcohol has therapeutic value, whereas those in the rural districts deny its value, "would seem to indicate that medicine is not yet a sufficiently exact science to be altogether independent of politics

The Trenton, N J, *Times* is strongly in favor of the resolution as passed 'Such a reasonable request' it says, "should be granted Patients who obtain whisky on prescriptions pay dearly for it and there should be no question as to its quality, nor of the quantity delivered"

The Philadelphia *Bulletin* after stating the case, believes that as long as the federal law recognizes the medicinal use of alcoholic liquors "there should be some law or body under the government competent to guarantee that the medicinal liquor shall be pure—at least, that it shall not be poisonous

Conscienceless profiteering puts the price of alcoholic stimulant beyond the reach of many a patient for whom it is prescribed More utter lack of conscience on the part of those in the trade makes it impossible to get good, or even safe, liquor at any price There is a risk that ought not to be tolerated in the supply of any preparation that may be used as a medicine. These dangerous conditions must be remedied, and if there shall be no other adequate means offered, the suggestion of government control of the medicinal supply may make a strong bid for popular favor

The Philadelphia *Inquirer* also is strongly in favor of the resolution "This is a perfectly feasible plan it says, and it might well be adopted Nothing could well be worse than the present situation It is clear that the prohibition officials have muddled it inexcusably The law as it stands presumes to limit the quantity of liquor a physician may prescribe in a given case thus often giving him a choice between breaking the law and letting the patient die This is bad enough, but to leave him without the assurance that the liquor he is allowed to prescribe is not rank poison is worse The government will not be blameless in this matter if it refuses to act , and The Erie, Pa *Times* supports the attitude of the *Inquirer* and requotes its views

The Chicago *Tribune*, heading its editorial, 'Physicians are not Bootleggers," supports the action of the House of Delegates vigorously, saying in part 'If an honest doctor prescribes whisky for a patient it is because he thinks the patient needs it If so, he is entitled to decide how much the patient needs and not to be told by the law that the requirement is not more than a pint every ten days Physicians differ as to the value of alcohol as medicine. They differ in many particulars of practice The community licenses them to practice medicine after a determination of their qualifications The community does not tell them how they shall write prescriptions If a physician dishonestly writes whisky prescriptions he is in that operation a bootlegger, and is an element against the enforcement of prohibition just as any other bootlegger or rum runner is The direct sale of liquor by government agencies on physicians' prescriptions is theoretically good How it would work we do not know The government has not kept its prohibition activities free from fraud and dishonesty by a long shot'

The Peoria, Ill, *Transcript* believes that "the principle is sound and if put into practice would afford grateful relief from the present system of crisscross bootlegging, fake medical prescriptions and blackmail Neither the reputable physician nor the reputable druggist has any desire to handle whisky under present conditions Prescribing "whisky" is a plunge in the dark Nobody knows what it is Good whisky in bond is widely scattered, and the government is being robbed of revenue and respect by fake raids, burglaries and 'gagged watchmen' Such sentimental objections as might be urged against making Uncle Sam a bartender would be easily overcome by the practical benefits of direct distribution

For many years, Uncle Sam reaped an enormous revenue from spirits and none was heard to complain If he can restrict the traffic in poisonous concoctions by donning an apron and tending bar, he will please large areas of America which are weary of law violations, covin, trickery and hypocrisy The resolution of the American Medical Association is in the form of an appeal to Congress and the Secretary of the Treasury It is worthy of serious consideration Under the eighteenth amendment, there is no ban on intoxicating liquors used for other than beverage purposes

'Reputable physicians and druggists desire to comply with the law without the hazard of being set down as bootleggers or sneaks If the government sells whisky, it will be known to whom it is sold Responsibility will be centralized, and people entitled to liquor will get a pure article at a fair price

The concentration of all bonded liquors in reserve districts under adequate guard and government distribution would not solve the whole liquor question, but it would obviate fake robberies and stiffen respect for the law The law needs respect more than the booze-fighter needs whisky"

The St Joseph, Mo, *Gazette* and the Moberly, Mo, *Democrat* strongly endorse the action of the Association both on prohibition and on the Sheppard-Towner Maternity Act

The American Medical Association," they say," at its meeting in St Louis seems to be in favor of the Canada plan of handling spirits A resolution favoring the handling of all whisky by the government and its distribution to physicians for medical purposes was adopted by the Association The Association also took a shot at the maternity law now being urged by a lot of old maids These two resolutions are remarkable when we consider the fact that the medical profession is closer in touch and ought to know more about both matters than any other class of men in the entire country Is it possible that the day of propaganda is riding to a fall, and sanity and common sense are again to rule? No body of men can do more than the medical profession to steady the tide of legislation and eliminate hysteria therefrom. It is evident however, that there was no politics in the national Association and the members voted their honest conviction on questions coming before the Association"

The St Louis *Star* is pleased to observe that the first move of the American Medical Association at the St Louis session was to clear away the difficulties imposed upon the medical profession by the liquor prescription business "Poor liquor furnished by druggists,' says the *Star* 'on genuine medical prescriptions is one difficulty, good liquor furnished on the prescriptions of bootlegging physicians is another Of the two the latter is more harmful both to the public and to the medical profession. Government control of liquor sales to druggists would throw a safeguard around the medical profession, on both of these points, provided the physi-

cians will agree to a drastic limitation upon the number of prescriptions that may be written, and will unite to eliminate the indiscriminate prescribers of both liquor and narcotic drugs" .

The Modesto, Calif, *News* believes that "the government control over the medicinal liquor business would prevent evasions or pretense"

Book Notices

THE PLACE OF VERSION IN OBSTETRICS By Irving W Potter M D F A C S Obstetrician in Chief Deaconess Hospital and St Mary s Maternity Hospital Cloth Price $5 Pp 138 with 42 illustrations St Louis C V Mosby Company 1922

The two parts of this book comprise, first, an incomplete historical sketch of version, and second, an exposition of the writer's method of practice, which he has evolved from the descript ons of many dead masters of the subject, and which he has named, "Potter s Version" The historical data are essentially—though not always—accurate, and there is an evident absence of actual reference to the authorities, who are responsible for steps included in the author s method, leading to the implication that he, de novo, had originated every detail

Furthermore, the history of the method seems to be utilized as a defense for its promiscuous use The stretching of the perineum is not new Karl Braun appreciated the necessity of overcoming the resistance of the tense perineum Clifton Edgar amplified it, and most teachers of obstetrics have, for ten or fifteen years taught the necessity of ironing out the perineum as a preliminary to version or to any extraction Guillemeau, the student of Pare, always used the right hand, being dextral, the author, being left-handed invariably uses the left hand Therefore, necessity demanded that the writer should be different It is so evident that it is appropriate to select the hand which would most conveniently reach the feet, depending on the position of the fetus, that Pare himself practiced it, and the choice of hand has been dictated by this fact ever since The illustrations (Figs 36, 38 and 39) clearly show the awkwardness of the technic when one hand is invariably employed The author advises that the hand shall be insinuated between the membranes and the uterus until the feet are reached this procedure was first suggested in 1694 by Peu, was advised by Smellie, and was modified by Huter in the middle period of the last century While the objections to this method of entering the uterus were distinctly valid in preantiseptic days, there is even now more than theoretical objection Levret's insistence that the membranes should be ruptured at the os is still sustained The author brings down both legs, according to the real originator of version, Pare, who first brought down one leg, and then the other

Mme du Tertre, in 1677, clearly saw the advantages of bringing down only one leg and was the first to recommend that such be the course in a version a complete breech is a better dilator than a footling and much more so than a double footling A double footling reduces the dilating volume of the breech fully one fourth Up to the time of J L Baudelocque, more than a hundred years ago, either the arms were not brought down at all, as advised by Deventer, or the anterior or posterior arm was disposed of as the exigencies of the case warranted Baudelocque showed that usually the posterior arm more readily could be brought down first For some years the Harvard School has advocated the primary delivery of the anterior arm Here, again, the author has not originated a step

The text following the three chapters on the history of obstetrics is essentially a reprint of an article appearing in a medical journal a year ago Certain data are added, including twenty-three illustrations, some of which are not anatomically correct Figure 15 is such a manifest error of art that one wonder why it is included The technic, as has been said, offers nothing that is new, yet on page 112 is this sentence "This merely serves to emphasize the fact that the operation must at all times be done only *in properly selected cases*' (the author's italics) One wonder where the selection is employed, on reading that in the last 2,243 cases in the author's practice, version was done 1,858 times Moreover, in the total number of women, cesarean sections were done 180 times—1 in 12 4 patients Indications are not definitely stated—or, better, the indications mentioned were discovered in the course of the version, and therefore were not indications in the usual conception of the term Indications must be lacking, fundamentally they must be absent when an operator indiscriminately selects two operations which conserve his time—and gives the woman small chance to prove her inherent obstetric prowess The obtruding thought suggested in the foreword leads to the belief that the author's indications are specious, including possibly conservation of self in a task too arduous for one man "Therefore, any advance in the practice of obstetrics which will conserve the strength and well being of the attendant and shorten the amount of time necessary for the completion of a given task, provided that safety and efficiency are in no way lessened or sacrificed," he says, 'is worthy of consideration even upon this ground alone" Nothing concrete is presented, but the inference is that the author never breaks a bone or organically injures the child, though in the original article he states that he never broke a bone, and in another place that he never looks for such injuries, as they do not occur 'Seek, and ye shall find' saveth the prophet This is especially worthy in view of Runge's findings that in more than 90 per cent of babies dying after breech extraction (twice as frequent in secondary as primary breech cases) there are gross lesions which caused the deaths

A small book like this primarily a reprint of journal papers deserves small recognition, but the teachings inculcated are so extreme that it is highly important that comment be made The word that artificial delivery by version, and cesarean sections done in 8 per cent of women, is safer than normal labor is entirely foreign to fact The teaching, as given in this book, is dangerous and reprehensible, a rational sane, obstetric thought is imperatively needed if conservation of mother and child are to be realized

ÉTUDE SUR LE TRAITEMENT DE LA TUBERCULOSE PULMONAIRE Par le Docteur C M Desvernine Docteur en Medecine des Facultés de Paris de New York et de Madrid Paper Price 5 francs Pp 78 Paris L Expansion Scientifique Française '

The pages of this work are devoted, when not otherwise occupied by the rather numerous quotations, to a report on an experiment and on a clinical study In the experiment mentioned, a donkey was confined in a pneumatic chamber for a period of seven months The air pressure maintained in the chamber corresponded to that of 6 000 feet altitude At the end of the seven months a study of the blood elements was made, a comparison of the findings with those of the animal's blood before the experiment was begun disclosed a large increase in the number of erythrocytes, leukocytes and hemoglobin a result in line with the reports of other observers The material of the clinical study consists of a number of cases treated by an emulsion of sputum The results were not particularly noteworthy, and offer nothing new

CHIRURGISCHE OPERATIONSLEHRE FÜR STUDIERENDE UND ARZTE Von Prof Dr Friedrich Pels Leusden ord Prof der Chirurgie und Direktor der Chirurgischen Universitätsklinik und Poliklinik zu Griefswald Geh Med Rat Third edition Paper Price 200 marks Pp 800 with 778 illustrations Berlin Urban & Schwarzenberg 1921

The compilation of a work on operative surgery is a difficult and commonly an unsatisfactory task chiefly because operative technic cannot successfully be taught from a book This work is open to the criticism of being unnecessarily voluminous and of containing much obsolete material The illustrations are mostly pen and ink drawings of poor quality, and the majority fall short of the purpose for which they were intended The book could serve the single function of a catalogue of surgical procedures To the inexperienced it would be of some help, a well-trained surgeon could find little in it to interest him

Ignorance No Defense Under Narcotic Law—Purpose of the Law

(United States v Balint et al (U S) 42 Sup Ct R 301)

The Supreme Court of the United States, in reversing a judgment that sustained a demurrer to the indictment in this case, says that the indictment charged the defendants with unlawfully selling to another a certain amount of a derivative of opium and a certain amount of a derivative of coca leaves, not in pursuance of any written order on a form issued in blank for that purpose by the commissioner of internal revenue, contrary to the provisions of Section 2 of the act The defendants demurred to the indictment on the ground that it failed to charge that they had sold the inhibited drugs knowing them to be such But the statute does not make such knowledge an element of the offense, and this court has held that, in the prohibition or punishment of particular acts, the state may, in the maintenance of a public policy, provide that he who commits these acts shall do so at his peril and will not be heard to plead in defense good faith or ignorance Many instances of this are to be found in regularity measures in the exercise of what is called the police power, in which the emphasis of the statute is evidently on achievement of some social betterment rather than the punishment of the crimes Again, when one deals with others and his mere negligence may be dangerous to them as in selling diseased food or poison, the policy of the law may, in order to stimulate proper care, require the punishment of the negligent person, though he is ignorant of the noxious character of what he sells

It is evident from a reading of Section 2 that its emphasis is in securing a close supervision of the business of dealing in these dangerous drugs by the taxing officers of the government, and that it merely uses a criminal penalty to secure recorded evidence of the disposition of such drugs, as a means of taxing and restraining the traffic Its manifest purpose is to require every person dealing in drugs to ascertain at his peril whether that which he sells comes within the inhibition of the statute, and if he sells the inhibited drug in ignorance of its character, to penalize him Congress weighed the possible injustice of subjecting an innocent seller to a penalty against the evil of exposing innocent purchasers to danger from the drug, and concluded that the latter was the result preferably to be avoided Doubtless, considerations as to the opportunity of the seller to find out the fact and the difficulty of proof of knowledge contributed to this conclusion

Time of Origination of Disease Under Insurance

(Cohen v North American Life & Casualty Co (Minn) 185 N W R 939)

The Supreme Court of Minnesota, in affirming an order denying the defendant a new trial after the plaintiff obtained a verdict on a policy of insurance says that the policy promised indemnity for a disability coming solely as the result of disease which shall originate and begin after this policy shall have been in continuous force for 30 days" The policy was issued on November 15 December 19, the insured became ill and called a physician December 25 he went to a hospital, and, December 28 an operation was performed One of the surgeons who assisted at the operation gave the cause as postoperative adhesions, and said that the insured was also afflicted with cholecystitis Recovery was made Six years before, the insured had had an operation for appendicitis Thereafter he was well Until his attack of December 19, he had not been sick There was medical testimony that would justify, if not require, a finding that the trouble came at least in part from postoperative adhesions existing prior to the policy

The rule of construction was the usual one It must be favorable to the insured The insurer intended to give and the insured expected to get indemnity if illness or sickness came after the policy had been in force for 30 days They were not concerned with the latent or remote cause of it The cause of the disease insured against was not mentioned in the policy as a condition of liability The time when the disease should 'originate and begin" was made important The parties had in mind, as the subject of indemnity, disability from illness or sickness or disease first manifesting itself or becoming active after the 30-day period For this the policy promised indemnity It did not exempt the company from liability because the medical cause of the disease causing disability antedated the expiration of the period A construction making the time of the medical cause of the outbreak of the disease determinative of liability, irrespective of actual illness sickness or disease, as commonly understood, would make health insurance subject to uncertainty, unattractive to those wanting reasonable health insurance protection, and less marketable The policy issued by the defendant was fair to the insurer and the insured As the court construes it, the defendant was liable, though the medical cause of the disease existed prior to the policy, if the disease or sickness did not manifest itself until afterward So the ordinary man wanting health protection would understand it In other words, the court holds that a policy of health insurance giving indemnity for disability resulting from a "disease which shall originate and begin after this policy shall have been in continuous force for 30 days covers a disease first manifesting itself after such time, although the medical cause antedated it

Suing Physician and Employer and Releasing Latter

(Stachlin v Hochdoerfer (Mo) 235 S W R 1060)

The Supreme Court of Missouri, Division No 1, says that the plaintiff while in the employ of a manufacturing company, suffered a fall in which his right leg was broken near the ankle, the flesh being mangled and crushed, after which blood poisoning set in, and the leg had to be amputated He thereafter sued the defendant for alleged malpractice in the treatment of the leg On the same day, he sued the manufacturing company for damages for the personal injuries which he sustained, including the loss of the limb About four months later, he instituted a second suit against the company, in which he sought a recovery on account, among other things, of the alleged unskilful and careless acts and omissions of the company and the surgeons selected by it in the treatment of the injured leg Subsequently, for a recited consideration of $1,300, he released the company from all claims growing out of or in any wise connected with his injury His first suit against the company was dismissed On the same day his second suit against the company was dismissed on the execution by him of a paper which stated that, in consideration of $50 paid to him, he released the company from, among other things, any claim growing out of any treatment which the company caused, or failed to cause, to be rendered to him, reserving the right to proceed against the physicians to recover any amount which he may have suffered from their negligence in attending him

At the beginning of the trial against the defendant physician the plaintiff admitted the execution of the two papers on which his two suits against the manufacturing company had been disposed of, and the defendant offered in evidence the two papers and the petitions in the suits to which they respectively referred Thereupon at the request of the defendant the trial court directed a verdict in his favor, the court announcing that it did so because the plaintiff had accepted a sum of money from the manufacturing company in full satisfaction of all injuries resulting from the accident, including the loss of his leg But the judgment rendered on the verdict in the defendant's favor is reversed by the supreme court which goes on to say that, if the trial court's construction was the proper one, no fault could be found with its conclusion that the plaintiff was not entitled to receive compensation again for the same injury But while under the allegations severally of the petitions, in the first suit against the company and that against the defendant physician, the company and the physician was each liable to the

plaintiff for the loss of his leg, they were not joint wrongdoers, they were acting independently of each other their several wrongs were committed at different times, and the wrongful act of each, being several when committed did not become joint because its consequences united with the consequences of the other Each was liable, therefore, only to the extent of the injury done by himself Still, the receipt of full satisfaction from either for the injury for which both were liable would bar the plaintiff from recovering from the other for the same injury

The two papers executed by the plaintiff when read together, clearly indicated that he and the manufacturing company considered and treated the suit first filed against the company as one for the original injury only and the second suit as one for the loss of the leg The second suit against the company was based on the theory that the physicians who treated the plaintiff's broken leg were its agents or employees, for whose negligence or unskilfulness it was liable Under this view the company and its physicians, so far as there was negligence in that respect, were joint wrongdoers, and an acknowledgment of satisfaction from one for the injury inflicted by them both would release the other But a reading of the paper disposing of that suit made it manifest that it was a covenant not to sue, and nothing more In other words the supreme court holds that the papers executed by the plaintiff when properly construed, operated as an acknowledgment of satisfaction for the original injury and a covenant not to sue the manufacturing company for the loss of the leg Therefore, the judgment for the defendant physician should be reversed, and the cause remanded

Quarantining of Place and Tearing Down of Placard

(Ex parte Cul er (Calif) 202 Pac R 661)

The Supreme Court of California, in discharging a writ of habeas corpus and remanding to custody the petitioner for the writ, says that she had been convicted of the commission of a misdemeanor, and fined with the alternative of imprisonment for tearing down a "diphtheria contract" placard which had been affixed to her premises declaring them to be in a state of quarantine The complaint against her alleged that the state board of health had issued an order directing the quarantine of the petitioner's niece, who was a minor child residing at the petitioner's home, for the reason that the child had come in contact with diphtheria patients and carriers of the disease, the affixing of the placard to the premises, by a police officer, and the removal of the placard from the premises in the presence of the officer If the tearing down of the placard under the circumstances alleged constituted a misdemeanor under any statute of the state, the complaint must be held to charge the commission of a public offense And if the quarantining of these premises was a proper act in pursuance of the order received from the state board of health, then the petitioner's act in tearing down the placard was punishable as a misdemeanor under the Public Health Act

There can be no doubt that by virtue of the broad power conferred by Sections 2979 and 2979a of the Political Code of California and by the Public Health Act, the state board of health has power to order the quarantine of persons who have come in contact with patients suffering from, and with carriers of, contagious diseases, whenever in the judgment of the board such action shall be deemed necessary to protect and preserve the public health But the petitioner pointed out the distinction between quarantining a place and quarantining a person, and there may be cases in which buildings are quarantined, as distinguished from persons For instance, when smallpox patients have been removed from a building to a pesthouse, the building itself should be quarantined until disinfected, but this does not alter the fact that the ordinary method of quarantining persons is by confining them to their residences and by giving notice to the people outside and inside that there is to be no going out nor coming in Moreover, it is perfectly apparent, from a consideration of the quarantine rules incorporated in the Public Health Act that this statute recognizes that the method of quarantining a person is to quarantine the place in which he lives Otherwise, the quarantine is spoken of as an arrest of the person

Section 2979 of the Political Code provides that the state board of health may establish and maintain places of quarantine or isolation, but how can it be seriously contended that a mere order directing that a person be quarantined is intended to mean that that person shall be arrested and placed in such an isolation hospital, rather than quarantined by being confined to his residence? Of course, taking possession of the person in the exercise of the powers of the state over health matters would be a method of quarantine, but obviously that cannot be said to be the only method of quarantining a person, when the statute clearly indicates that when a place is quarantined the people therein are confined thereto and cannot leave For instance, in the case at bar, if the state board of health had ordered the quarantining of the place of residence of the petitioner, it would thereby have subjected the proceedings to the very absurdity which the petitioner contended for, namely that the place was quarantined and the person was not The order of the state board of health to quarantine the person of the petitioner's niece meant that she must be confined to a given place and kept out of the community This was obviously accomplished by putting the appropriate notice on the house which she occupied, as required by statute

An Adequate Remedy at Law Without Injunction

(People Uni ersal Chiropractors Ass n et al (Ill) 134 N E R 4)

The Supreme Court of Illinois, in affirming a decree dissolving a temporary injunction and dismissing the bill, holds that there was an adequate remedy at law The court says that fifty-two defendants were named all of whom, it was alleged were chiropractors treating human ailments without a license, and belonging to what was known as the Universal Chiropractors Association, that some of them had been convicted of treating human ailments without a license, and sentenced to pay fines or to imprisonment, but, after paying their fines or serving their terms of imprisonment, had returned to and continued their practice, that the association collected dues from which fines and costs assessed against members were paid, that, by reason of a conspiracy of defendants to defy the laws and continue their unlawful practice of treating human ailments without a license which is prohibited by law and is a business subversive of the public health and morals the defendants had brought about a condition, throughout the state, of disrespect and contempt for law, and threatened to, and would, continue in such conduct unless enjoined The theory of the bill was that the conduct of the defendants amounted to a nuisance which a court of equity would enjoin, that the defendants were maintaining an organization for the aid of those belonging to it who were violating the law, and proposed to continue such violation Since the bill was filed, the case of People v Love, 298 Ill 304, 131 N E 809, has been decided by this court, and provisions of the Medicine and Surgery Act of 1917 relative to the qualifications and licensing of chiropractors have been held invalid But, even if the entire act of 1917 was rendered invalid by that decision, and the act of 1899 is still in force, all the bill alleged the defendants proposed to do was to continue to practice without a license which would be a misdemeanor for which punishment is provided and an adequate remedy at law exists The possibility that many persons will violate the law and many suits will be required to enforce it does not warrant relief by injunction The jurisdiction of a court of equity to issue an injunction in some cases to prevent a multiplicity of suits is not determined by the number of suits Multiplicity is not synonymous with multitude, and there must be some other ground of jurisdiction besides mere number The circumstances must be such that the remedy at law will be regarded as inadequate If the defendants, or any of them, are arrested and charged with committing a criminal offense they have a constitutional right to a trial by jury in determining their guilt, and to sustain the injunction here sought would deny them that right

(Concluded from page 1990)

Roentgen-Ray Treatment of Toxic Goiter

DRS J H MEANS and G W HOLMES, Boston Of forty-four cases of exophthalmic goiter, definite improvement was secured by roentgenotherapy in twenty-eight Sixteen showed little or no improvement, eight of these patients later came to operation and were apparently cured Of the twenty-eight in which there was improvement, there were thirteen who were apparently cured, and fifteen who were improved but not rendered entirely free from hyperthyroidism No patients seemed to be made worse by the treatment Two patients improved but not cured were operated on later One of these died after operation Of the twelve toxic adenoma cases treated by roentgen rays, all showed improvement and five patients were apparently cured Two of the exophthalmic and one of the toxic adenoma cases developed myxedema during roentgen-ray treatment, which was promptly relieved by thyroid administration, and in the two exophthalmic patients the depression was only temporary, as thyroid was later discontinued without a return of myxedema In those cases of exophthalmic goiter which respond to roentgen rays there is a rapid fall in pulse (average from 115 to 89) and in basal metabolism (average from + 55 to + 21 per cent), and a corresponding gain in weight (average of 9 per cent) in the first four months of treatment, during which time they receive on an average five treatments In some cases the curves come to a normal level, in others they do not In the latter further roentgen-ray treatment is not strikingly satisfactory except in the cases which show a definite relapse, in these a second course of treatment may act as did the first We have as yet found no method of predicting which cases will respond to roentgen rays The results in toxic adenoma are similar to those in exophthalmic goiter In general, we feel that roentgen rays may cure certain cases, that it may improve others, that for this reason it has its place in the treatment of toxic goiter If it does not secure good results in a few months, surgery should be employed Some patients who are not cured by roentgen rays are rendered better operative risks A combination of roentgen rays and surgery will sometimes accomplish more good than either form of treatment alone To make a proper use of the roentgen rays in the management of toxic goiter, its limitations must be recognized and, when necessary, it should be combined intelligently with surgical procedures

Irradiation Treatment of Leukemia

DR FRANCIS CARTER WOOD New York The study of the results of irradiation of patients with leukemia has shown that myelogenous cases yielded easily and rapidly to either radium or the roentgen ray, and some lymphatic cases responded well This is contrary to experience recorded in the literature Patients with good red cell counts did better than anemic persons Children did badly, tended to develop hemorrhagic conditions, and died early, even though the spleen, nodules and lymph cell count were brought down In some adult cases the blood picture was brought to approximately normal by irradiation, but the case progressed rapidly to a fatal ending No relation was found between the blood count of the patient when first seen and the course of the disease Some myelogenous patients showed white cells from 500,000 to 700,000 per cubic millimeter, yet with irradiation remained alive and in working condition for three or four years Transfusions from young, robust adults are often helpful There is no difference between the effects of radium and the roentgen ray, as at present used A high voltage roentgen ray is now used In the early stages of myelogenous leukemia, irradiation is confined to the spleen, but in advanced stages life is sometimes prolonged by irradiation of the spleen, long bones, vertebral column and ribs The terminal stages of the disease are marked by hemorrhagic conditions in the viscera, and sometimes intradurally Often death follows extraction of teeth with accompanying hemorrhage

Treatment of Tonsils by Radiation from Radium Salts

DR FRANCIS H WILLIAMS, Boston Radium irradiations have a selective action on lymphoid tissue, of which the tonsils are largely made up Fifty milligrams of pure radium bromid was applied in a suitable container, directly first to one tonsil, then the other, for from ten to twenty minutes to each tonsil, according to the filter used, and the condition of the tonsil and of the patient The method of carrying out the treatment is based on measurements, made with a fluorometer The method has a remarkable degree of safety, if properly carried out, as the action of the remedy is largely exerted only where it is needed Therefore, this remedy can be used without causing any harmful effects, either immediately or remotely No patient was required to modify his usual diet or lose time from work

DISCUSSION ON PAPERS OF DRS MEANS AND HOLMES, WOOD AND WILLIAMS

DR THOMAS MCCRAE, Philadelphia I wish to ask Dr Means his opinion as to operation on the thyroid gland which has received roentgen-ray treatment Some surgeons are very emphatic in stating that operation after irradiation is sometimes very difficult If this is true, it is very important for us to decide which patients are likely to be helped by the roentgen rays and which ones should be operated on without irradiation The communication of Dr Williams is a very important one We are apt to think of the tonsil removal as a minor operation, but the total number of accidents is large, although small relatively to the number of patients operated on The number of cases of pulmonary abscess following tonsillectomy is surprisingly large If we have treatment which obviates the need of operation, it is certainly a great advantage

DR. H S PLUMMER Rochester, Minn About twenty years ago I saw cases treated by the roentgen ray and was enthusiastic about the results After a while I lost my early enthusiasm, and ever since then I have been trying to interpret the results of treatment of these cases Dr Means has presented some work which points to the fact that the roentgen ray is of benefit in these cases He has the same trouble I had—he has no controls for his results Would the case not have run the same course if he had never used the roentgen ray? Let us see what happens in exophthalmic goiter These cases follow a definitely normal course I recorded in months the length of time from the onset of the trouble to the time the patient came under observation I divided the year into periods of three months first second, third and fourth three-month period Sixty-two per cent. of the patients came under observation within the first period in the next period 1 per cent came under observation, 20 per cent at the fifth month and 1 per cent in the last period There is only one interpretation People with exophthalmic goiter are going to have a pronounced curve for the better, and they come under observation about that time The course of exophthalmic goiter up to the end of the first twelve months is up then down If one gives them cold water at this stage one will get the first shot down Whatever is given will get results No man knows the normal average course for exophthalmic goiter

DR FRANK BILLINGS, Chicago Many years ago I had a large experience in the treatment of leukemia with the roentgen ray My study showed among other things that applied to any local cutaneous surface, it produced a leukolytic sub-

stance in the blood The serum of the treated patient dissolved the white blood cells in vitro, while the serum of an untreated patient had no such effect The resolution of the spleen occurred more rapidly when the rays were applied to the skin over the spleen I found that a combination of roentgen ray and benzene was of greater effect than either one alone Approximately 100 patients with acute and chronic leukemia were treated between 1905 and 1914 There is no doubt that the life of many of these patients was prolonged by the treatment, but the final end-result was death For twelve years the clinic kept in touch with a laundress who suffered from chronic lymphoid leukemia She would not submit to roentgen-ray treatment, and the medication consisted of small doses of arsenic with iron Her health remained good enough to enable her to carry on her work This is an example of the long duration of this disease in some patients, and indicates that meddlesome treatment may do more harm than good

DR J H MEANS, Boston In answer to Dr McCrae's question, I should say that it depends on what surgeon you ask Drs Porter and Richardson say that in their experience previous irradiation does not make operation more difficult Dr Plummer's objection to our conclusions cannot be met directly In a sense he is perfectly justified in making it We cannot get data on untreated cases to serve as controls, because it is not legitimate to refuse treatment to patients with exophthalmic goiter for the mere purpose of studying the course of the disease The absolute proof of the effect of therapeutic agents will come only when the disease has been produced experimentally By clinical studies such as ours, then, we cannot expect proof positive, nevertheless, they are worth making They give evidence as to the beneficial effect of the roentgen ray, which is highly suggestive if not absolute proof Spontaneous recovery occurs in exophthalmic goiter but it would be very unlikely that two out of three cases should be started on roentgen-ray treatment at the precise moment they were starting a rapid spontaneous improvement It is possible, but distinctly improbable

DR F C WOOD, New York I have never secured leukotoxin We have worked on normal blood, giving thirty or forty erythema doses in the extremity employed and we never got destruction of the normal cells Leukotoxin cells are extremely sensitive, even if no roentgen ray is used, and it would be hard to demonstrate their production by the roentgen ray In laboratory experiments we did find lipase ferments brought out by exposure to the roentgen ray The roentgen raying of bones in some of our cases has not produced as rapid a fall as in the spleen We should irradiate a definite area where hyperplasia is going on I have not noted benefit in the long bones as much as in the spleen I have seen bad results from the use of benzene The leukocytes begin to fall, but the patients die One patient abandoned as moribund, with only 50,000 blood plates and hemorrhage from the mouth, uterus and skin and really on the ragged edge, was subjected to irradiation, and she recovered to the extent that she lived three years and did hard farm work She died later following the extraction of some teeth I have the impression that these people do better if they are given sodium cacodylate subcutaneously, but I cannot prove it We know that arsenic has an effect on the leukemias The course of the disease is variable I have two cases of myelogenous leukemia which have lasted seven and eight years, respectively A chronic lymphatic leukemia has lasted six years The roentgen ray improves patients in an extremely bad condition, and brings them back into active working life I do not know that we give them longer life than in the slower, more chronic cases of leukemia I have never had a case treated that lasted seven years

Aneurysm of the Hepatic Artery

DRS JULIUS FRIEDENWALD and KARL H TANNENBAUM, Baltimore Sixty-five cases of this exceedingly uncommon affection are recorded in the literature We had one case A man, aged 48, became aware of a slight jaundice eight weeks before admission, which gradually increased, there was no pain, nor was anything else abnormal noted with the exception of a marked pruritus, loss of appetite and weight. A carcinoma was suspected, and the patient was admitted to the hospital for operation He had several collapses preceded by violent abdominal pains, and finally died suddenly before an operation was undertaken At the necropsy, 3 or 4 liters (quarts) of blood was found in the abdominal cavity, and an aneurysm of the hepatic artery the size of a small orange was discovered

Characterization of Various Forms of Endocarditis

DR EMANUEL LIBMAN, New York The types of endocarditis are rheumatic, syphilitic, acute bacterial, subacute bacterial and indeterminate The last named group includes cases usually having a history of true rheumatic fever, and is characterized by having very peculiar lesions on the valves and by the absence of Aschoff bodies from the heart muscle The so-called cases of terminal endocarditis also belong in this group These involve the left side of the heart in the main, the mitral valve There are no characteristic lesions in the heart muscle The cause is unknown The cause of rheumatic fever has not yet been discovered The specific lesion is the Aschoff body, but this lesion is found in only about one third of the cases that are clinically recognized as belonging to this group The Aschoff body is a perivascular lesion In rheumatic fever, a secondary infection by anhemolytic streptococci is found in 20 per cent of the cases The groups called bacterial are so designated because they are due to known bacteria The cases with an acute course are due, in the main, to hemolytic streptococci, pneumococci, staphylococci, the gonococcus and other organisms The subacute group is due, in more than 95 per cent. of the cases to anhemolytic streptococci (so-called *Streptococcus viridans)* The remaining cases are nearly all caused by the influenza bacillus Other organisms especially the gonococcus, can produce a subacute picture, and on the other hand the organisms found in the subacute cases may, rarely, be the cause of an acute type of disease The portal of infection in the acute cases is usually an evident purulent focus, in subacute cases a focal infection or possibly the intestinal tract cultivates the disease The acute cases should be named according to the etiologic agent that is found Subacute cases are best termed subacute *Streptococcus anhemolyticus* and *Bacillus influenzae* endocarditis One could shorten the terms and talk of subacute streptococcus and influenzal endocarditis

Gonorrheal Endocarditis

DR W S THAYER Baltimore Three hundred and twenty-seven cases of acute endocarditis, which came to necropsy, were studied In 133 of these the lesion was determined bacteriologically In forty-three cases blood culture during life was positive, making a total of 176 Twenty-two of these or 11.3 per cent were gonococcal Age incidence was from 9 to 42 years The relation of the onset of endocarditis to the period of acute infection was not often clear Of the twenty-two cases in seven, or 31 per cent, there was arthritis The symptoms were those of grave septicemia fever chills sweats in irregular recurrence The blood showed rapidly increasing anemia and high leukocytosis The duration of the disease was from three weeks to eight months, the average being 9.7 weeks From a clinical study of the cases it would seem that gonococcal endocarditis has a malignancy between that of malignant streptococcus, staphylococcus and pneumococcus, on the one hand, and that of the slower viridans and influenzal infections on the other The anatomic lesions were in the form of large, yellow or white, crumbly vegetations, the left side of the heart being more frequently involved Right sided lesions, however, were more frequent than usually reported The aortic valve was most commonly affected The gonococcus infection usually involves healthy previously undiseased valves The disease is generally a progressive infection tending toward a fatal termination but milder cases may occur with progress to recovery The latter, however, are relatively rare.

Clinical Observations on Heart Block

DR PAUL D WHITE, Boston Intraventricular block is almost as frequently seen in a large medical clinic as is

auriculoventricular block, 4 per cent having been found in 3,219 cases observed at the Massachusetts General Hospital, as compared with 4.8 per cent. Complete auriculoventricular block showed one-fifth the frequency of unquestionable partial auriculoventricular block. Bundle branch block of high grade made up slightly less than one third of the total number of cases of intraventricular block. Sino-auricular block was rarely found, less than half as often as complete auriculoventricular heart block. Arteriosclerosis was apparently responsible for the majority of the cases of complete auriculoventricular block and of intraventricular block of all degrees, but especially of bundle branch type, in which it figured as the chief factor in more than 80 per cent. Syphilis was a probable factor in sixteen of 156 cases of auriculoventricular block, and in eleven of 130 cases of intraventricular block. Antisyphilitic treatment in a number of the cases followed has not abolished the block, although disappearance of heart block under treatment has been reported, and I have seen one such case. In the series of partial auriculoventricular block cases, digitalis seemed to be chiefly responsible in more than half, on a background of rheumatic heart disease more often than arteriosclerotic heart disease. Digitalis was also largely responsible for six of the eleven cases of "sino-auricular block." The characteristic flattening or inversion of the T wave of the electrocardiogram was here very helpful in analysis of digitalis effect. Less than one quarter of the cases of complete auriculoventricular block showed heart failure, either anginal or congestive, at the time of discovery, and also less than a quarter gave a history of Stokes-Adams attacks. The mortality from heart failure in the last seven and one-half years has been slightly higher in the group with intraventricular block than in the group with auriculoventricular block. Several of the patients with complete heart block were in fairly good condition some years after the discovery of the block, in fact, nine being in "good or in fair health" from one to seven years after the first electrocardiographic evidence of complete heart block. Four of the five patients surviving in fairly good health over five years after the discovery of the block were the four patients under 40 years of age. Heart failure was found more often in the patients with intraventricular block than in those with auriculoventricular block, *especially of the anginal type*. Angina pectoris was found about four times more often in intraventricular block than in auriculoventricular block. It appears from this study that intraventricular block is of greater significance than auriculoventricular block. For its detection, the electrocardiograph is essential.

Digitalis Effects in Cardiac Cases with Regular Rhythm

DR. HENRY A. CHRISTIAN, Boston: Mackenzie and others have so emphasized digitalis effects as occurring almost solely in cases with auricular fibrillation that there is a growing feeling that, unless the pulse is absolutely irregular and rapid, little is to be gained from digitalis therapy. My own view is that digitalis therapy, as a rule, has a striking effect on those changes in the patient which are brought about by cardiac insufficiency irrespective of whether the pulse is fast or slow, irregular or regular. In ninety-seven consecutive cardiac cases, forty had regular rhythm and fifty-seven auricular fibrillation. In those with regular rhythm there was a considerable digitalis effect obtained in 72.5 per cent. and in those with fibrillation in 75.4 per cent. There seemed to be little difference dependent on rhythm. A considerable digitalis effect was taken as a decrease of at least thirty beats a minute, a loss of 4 kg. (8⅘ pounds) in weight or a definite diuresis. In this group numerous patients with a slow cardiac rate showed excellent and some striking effects from digitalis therapy. Of those with slow rate some had a regular rhythm, while others were fibrillating. Loss of edema, as shown by drop in body weight and diuresis, are just as striking and fully as satisfactory results of digitalis therapy as decrease in heart rate, and both occur irrespective of the presence or absence of auricular fibrillation. In fact, loss of edema adds more to the patient's comfort than change in rate. This report demonstrates that striking improvement in symptoms and signs in cardiac patients occur irrespective of rhythm and rate, and consequently regular rhythm or slow rate is no reason for withholding digitalis from patients with cardiac insufficiency with the idea that digitalis therapy will cause little or no improvement.

Quinidin in Auricular Fibrillation

DR. T. STUART HART, New York: Of seventeen cases of auricular fibrillation treated with quinidin, fifteen were continuous fibrillation cases, two were cases of paroxysmal fibrillation. These were not selected cases. They were treated according to the ordinary hospital routine and were followed very closely by frequent electrocardiographic studies. The method of administering quinidin was the one usually employed. The patients were given two preliminary doses of 0.2 gm. each, twenty-four hours being allowed for evidence of susceptibility to develop. After this, 0.4 gm. was given three times a day. As soon as sinus rhythm had been reestablished, the drug was immediately discontinued. Of the fifteen cases of persistent fibrillation, five recovered to normal rhythm. In both paroxysmal cases sinus rhythm promptly followed the quinidin administration. In my experience, if quinidin was effective in producing sinus rhythm, this occurred within a few hours or, at least, not longer than sixty hours after beginning the drug. In reviewing the electrocardiographic curves, I have been impressed by the fact that those patients who in their control curves showed relatively large auricular waves were more likely to regain a normal rhythm. I have seen no dangerous results following the administration of quinidin. I gave quinidin only to those patients who had never received digitalis, or I withheld it for two or three weeks until I was sure that the heart was free from digitalis influences. The use of quinidin in combination with digitalis has been opposed on the ground that their pharmacologic activities are antagonistic. I have some electrocardiographic evidence which supports this view. Quinidin slows the auricle and increases the rate of the ventricle, while digitalis makes the auricle more rapid and slows the ventricle. These effects were observed in most of my cases. The clinical evidence of the antagonism of these two drugs is less evident.

Arsenical Treatment of Chronic Infectious Endocarditis

DR. JOSEPH A. CAPPS, Chicago: This group of cases is to be differentiated from rheumatic endocarditis and the acute ulcerative endocarditis. Eight cases with characteristic clinical symptoms showed positive blood cultures. All were given sodium cacodylate daily over a long period. Two patients died, four are well after intervals of from twenty-two months to eleven years, two are improved after an interval of three and six months, respectively. These results, along with certain experimental evidence, encourage the hope that the long continued use of arsenic has an inhibiting, if not a germicidal, influence on the causative organisms.

DISCUSSION ON PAPERS OF DRS. FRIEDENWALD AND TANNENBAUM, LIBMAN, THAYER, WHITE, CHRISTIAN, HART AND CAPPS

DR. JOSEPH L. MILLER, Chicago: It is difficult to determine just what should be included in this group known as subacute endocarditis. It should include, no doubt, cases which show very wide variations in intensity of symptoms—from the relatively low grade infections to a form which merges into acute septic endocarditis. There is one form of considerable interest: patients who enter the hospital with a history of an old endocardial lesion years previously and have gone along comfortably with good compensation, then without known cause their compensation is disturbed. They might pass as having a broken compensation due to an old lesion. Many will go for days without fever, and only at infrequent intervals have 99.2 or 99.6 F.—just enough to excite suspicion that an acute process may be present. I have followed several of these cases to necropsy and have been surprised to find a subacute form of endocarditis. In this group of cases the blood cultures are practically always negative. There is no enlargement of the spleen, and there are no emboli, and consequently no glomerular nephritis. At present we are

very suspicious when a patient enters the hospital with a history of an old lesion, but who has had good compensation for a time and has recently developed decompensation, that we are dealing with an acute process, and the presence of even a very moderate degree of fever helps to sustain this view.

DR. MORRIS WHITE, Minneapolis: I have been using small amounts of digitalis in auricular fibrillation, with fair success, but not so much as Dr. Christian reports. The margin between good digitalis effects and partial block is a narrow one. Dr. Hart did not state whether he had used quinidin after treatment with digitalis. Has he used it when the digitalis effects were wearing off?

DR. FRANK BILLINGS, Chicago: Richard Pearce found that sodium cacodylate in the animal is excreted in the urine as arsenous oxid. It appeared to be nontoxic. I began to use the drug in the treatment of chorea with good results. In 1905 I saw in consultation a boy, aged 10, who had acute rheumatic fever associated with a severe type of chorea and pancarditis, including pericarditis with serofibrinous effusion. The boy's condition was very serious. The first twenty-four hours 8 grains of sodium cacodylate was given subcutaneously in divided doses. Within thirty-six hours there was a marvelous change manifested by subsidence of the chorea, the disappearance of the fever and swollen joints and a practical resolution of the effusion within the pericardium. The drug was discontinued and within another thirty-six hours there was a complete recurrence of all the symptoms, including a renewal of the effusion within the pericardium. The drug was again given in the same dosage, and after the subsidence of the acute manifestation, which occurred again within forty-eight hours, it was continued in somewhat smaller dosage for a week or longer. Since that time I have continued to use the drug with the same positive good results in acute rheumatic pericarditis with effusion. Since then I have not found it necessary to perform paracentesis of the pericardium. This experience with the drug justified the belief that it had some specific effect in certain infections, notably acute chorea and acute rheumatic pericarditis. This experience also led to the use of the drug in chronic infectious endocarditis with *Streptococcus viridans* bacteremia. The drug is apparently nontoxic even when used in relatively large doses either subcutaneously or intravenously. I have given as high as 1 gm. intravenously every two or three days. No unfavorable toxic effect has been observed. I believe that a lesser dosage is quite as effective, and would advise those who use it to make the daily dose not greater than 0.6 or 0.7 gm., given either subcutaneously or intravenously in one dose.

DR. E. P. CARTER, Baltimore: I have long made use of Eggleston's dictum that 'the indication for digitalis is the degree of cardiac failure and not the cause." We have been studying the effect of digitalis in the presence of a normal mechanism with particular reference to its effect on the cardiac rate and the blood pressure. Patients showing evidences of marked cardiac failure have been put to bed and kept at rest without digitalis until the heart reached and maintained a rate at a constant level for each individual case. We then digitalized them and found in a large percentage of the cases in addition to the marked clinical improvement, a very striking slowing in the cardiac rate and even in some instances an actual shortening in the conduction interval and improvement in other phases of the galvanometric record, in addition to the fall in blood pressure. With the suggestion as to the possibility of digitalis being equally as dangerous as quinidin as a cause of sudden death, I cannot agree. Before the introduction of quinidin I attempted to see in how many cases of fibrillation I could, if possible, bring about a complete auriculoventricular dissociation by digitalis. I was successful in producing a complete dissociation in only three cases. Surely in these instances, were the danger from digitalis at all a real one, as suggested, I should have met with a catastrophe. One other point which should be brought out in connection with the action of digitalis in the presence of a normal mechanism is that following the administration of digitalis the greatest shortening of the cardiac muscle fibers coincides with the maximum degree of change in the T wave, and that the actual output of the heart per beat was increased in a large percentage of their observations. In reference to the use of quinidin, in our series of sixteen cases we have had two catastrophes of sudden death occurring shortly after the return to normal mechanism. In one case the postmortem disclosed the presence of auricular thrombi and numerous emboli, in the other a necropsy was not allowed.

DR. SOLOMON SOLIS-COHEN, Philadelphia: May I ask Dr. Christian whether he has any data concerning the relative numbers of cases of valve disease and cases of muscle disease without valve lesion among the cases in which he observed positive effects from digitalis? Also, whether he observed any difference in effect that seemed to be dependent on the presence of any special lesion of the valves? In chronic cases, at least, and whether or not there is fibrillation or flutter, I expect better results from long continued moderate dosage than from the newer method of enormous initial doses with lessening or omission later. Of course, I am not speaking of emergencies—they are a law unto themselves. Also, it is hardly needful to say that in the continued use of digitalis there must be periods of intermission and that the drug must be stopped when the indications for it no longer exist. Irrespective of the lesions and considering only the mechanics or dynamics of the circulation the indications or contraindications for digitalis are to be found in the advisability or inadvisability of slowing the heart, increasing the ventricular force, and improving the nutrition of the organ. To get this result there must, of course, remain a sufficient quantity of muscle substance capable of response to the influence of the drug. It will not revive the dead, and it will not be useful in cases of advanced muscular degeneration and it will do harm when there are certain forms of lesion in the atrioventricular bundles, but to look on fibrillation or disturbance of rhythm as the only or chief indication for its use is to ignore not only the clinical lessons of generations but also pharmacologic studies which cannot be set aside lightly.

DR. L. A. CONNER, New York: I would like to ask Dr. Libman whether he can give some idea of the proportion of his cases of *Streptococcus viridans* endocarditis that occurred in hearts with normal valves. I cannot recall ever having seen a case of viridans endocarditis which had not developed in a heart already the seat of some form of valvular damage. I have gradually gained the very definite impression that the chances of successful restoration and maintenance of a sinus rhythm is much greater when heart failure is present, if the patients have been thoroughly digitalized before quinidin is begun.

DR. ALFRED STENGEL, Philadelphia: I have not had the same experience with sodium cacodylate as mentioned by Drs. Capps and Billings. I think there might be danger in the heavy doses. Not all cases of endocarditis end fatally. I can refer to many cases in children up to the age of 12, in which there was an intermittent fever for three or four months, and ultimately the patient recovered.

DR. EMANUEL LIBMAN, New York: The studies made by Oppenheimer and Rothschild agree with those made by Dr. White as regards the infrequency of auriculoventricular block as compared with intraventricular (or arborization) block. Dr. White has well emphasized the value of electrocardiographic examinations for the diagnosis of intraventricular block. Occasional exceptions should not deter us from using a diagnostic method. It is necessary, of course, carefully to check up the electrocardiographic results by the clinical findings. Dr. Capps' results were obtained mainly in patients that had but little fever. It will be necessary to contrast the results in such cases with cases with the same grade of fever which have not been subjected to any but hygienic and dietetic methods of treatment. Arsenical preparations have been used quite extensively. The results cannot yet be analyzed.

DR. W. S. THAYER, Baltimore: There is a sharp line of distinction between the bacteria seen in ordinary endocarditis and those of the severe forms. There were four streptococcus cases in which the fever lasted thirteen weeks, and one pneu-

mococcus case lasting for the same length of time In sixty cases of *Streptococcus viridans* endocarditis there was no history of preexisting cardiac disease as far as we could judge in thirty-two patients

DR HENRY A CHRISTIAN, Boston As to whether patients had rest in bed for several days prior to digitalis therapy this has often been done so that we know that digitalis produces a marked effect beyond that produced by rest As to dosage, some had the large single, so-called physiologic dose, some had a modified large dosage, while others had a smaller dosage, such as 0 1 gm of powdered leaves of digitalis, three times a day The results were much the same by all methods, only, the larger the doses the sooner they became effective With regard to heart block, in patients with regular rhythm I observed no clinical evidence of such I think that, if Dr White had continued digitalis in his patients without reference to the occurrence of electrocardiographic evidence of slighter degrees of heart block, he would have obtained better results from digitalis in his cases As to whether these patients had valvular lesions, about two thirds were cases of chronic myocarditis without evidence of any organic valve lesion, but good effects also were obtained with digitalis in cases in which there were organic mitral and aortic lesions

DR T STUART HART, New York I have had no opportunity to study the cases in which the digitalis effects were passing off Our studies indicate a method which may furnish a means of finding out how digitalis and quinidin can be used together We saw no bad effects from the administration of quinidin At present, however, I feel that a drug so spectacular in its effects as quinidin should be used with the greatest caution

DR. J A CAPPS, Chicago The dosage of sodium cacodylate in my cases was never very large, from 2 to 4 grains a day over a long period, in preference to giving a very large dosage for a short period

DR. EMANUEL LIBMAN, New York It is very difficult to differentiate between the severe and the mild cases I do not believe that the temperature is always reliable, as we have often had patients die without high temperature

DR PAUL D WHITE, Boston It has been my experience that digitalis is much more effective in heart failure with auricular fibrillation (previously untreated) than in heart failure with normal rhythm (previously untreated)

Clinical Aspect of Studies on the Metabolism of Diabetes

DR ELLIOT P JOSLIN, Boston Prior to the introduction of treatment by undernutrition, the average urinary nitrogen excreted per kilogram of body weight for twenty-four hours was 0 265 gm After that time, for a considerably larger series of cases, the average urinary nitrogen excretion was 0 185 gm per kilogram of body weight for the twenty-four hours The average metabolism for the early series was + 12 per cent and for the later series — 11 per cent Comparison of the urinary nitrogen determinations with loss in body weight with metabolism and with the respiratory quotient suggest that protein metabolism alone does not control the total metabolism, that exogenous protein may be more stimulating to the metabolism than endogenous protein, that a very high nitrogen excretion in a severe diabetic may represent the prelethal rise, and that even such a diabetic may have the power to oxidize carbohydrate to a degree which is often not appreciated, but obviously should be utilized

Effects Produced on Diabetes by Extracts of Pancreas

DRS J J R MACLEOD, F G BANTING, O H BEST, J B CALLIP, W R CAMPBELL, A A FLETCHER and E C NOBLE, Toronto Researches on the action of pancreatic extracts have hitherto failed to take into account that there might be a powerful proteolytic enzyme which could destroy or digest any internal secretion also present We have sought to obtain the pancreatic secretion isolated from such a proteolytic ferment, and to study its independent action A highly potent product was obtained in small quantities from cattle fetus pancreas, which was termed 'insulin' This is harmless to man and to laboratory animals when given in proper dosage, but toxic in large proportions In seven cases of human diabetes mellitus, subcutaneous injection of insulin reduced the blood sugar to normal level with disappearance of sugar and ketone bodies from the urine The improved carbohydrate metabolism was evidenced by improvement in the respiratory quotient which rose decidedly within two hours, while the patients felt a marked improvement in symptoms and in general well being Laboratory experiments indicate that the pancreatic extract employed contained properties controlling carbohydrate and fat metabolism, yet its clinical results cannot be estimated Probably the dietetic treatment will still be foremost, but the extract promises to be of value in tiding the patient over those crises which are frequently uncontrollable by other means

Pathology of Human Botulism

DR A S WARTHIN, Ann Arbor, Mich Six cases of human botulism were studied, five arising from eating canned spinach and one from canned ripe olives The pathologic condition in all was the same The brains were removed shortly after death and showed a marked perivascular infiltration, hemorrhage in the vessels of the cortex and vascular edema Evidences of defensive reaction were rare in the cortex, and chiefly seen in the meninges The cases all presented a similar feature of antemortem gas production within the brain, and the formation of small gas cysts containing bacilli, morphologically resembling those of *B botulinus* These cases present evidence that human botulism may be an infection as well as an intoxication

Diagnosis and Treatment of Intestinal Tuberculosis

DR LAWRASON BROWN, Saranac Lake, N Y We studied 1,036 cases with regard to the presence or absence of intestinal tuberculosis, and found 146 cases positive Five per cent of these occurred early in pulmonary tuberculosis The cases were studied both fluoroscopically and roentgenographically Segmentation and dilatation of the small intestine is suggestive of tuberculous enteritis, in contradistinction to tuberculous colitis As operative results in these cases are rather poor, we looked for other methods of treatment We tried the ultraviolet lamp The roentgen ray has no effect on uncomplicated pulmonary tuberculosis, but it has considerable effect in clearing up the colon in tuberculous colitis, and after the colon has cleared up the lungs tend to clear up and the patient is much better

Experiences in the Treatment of Lobar Pneumonia by a Serum Free Solution of Pneumococcus Antibodies

DR. LEWIS A CONNER, New York The treatment is based on the capacity of bacteria to absorb their antibodies from the specific serum Pneumococci were exposed to human polyvalent serum, and the sensitized bacteria were then treated with mild alkaline salt solution The bacteria were washed to remove the serum, and, after being standardized, were centrifuged and used therapeutically The intravenous injection of antibody solution was given as soon as the diagnosis was established, without waiting for typing One hundred and fifteen cases were treated There was the usual foreign protein reaction—a severe chill and rapid rise of temperature the patient became cyanotic and the pulse rapid and small, then the temperature fell rapidly and the patient began to improve The thermal response is very severe There is a striking fall in leukocytosis, which sometimes rises again The physical signs did not follow the course of the temperature In one case of hyperpyrexia, death was probably due to the injection Three other fatalities occurred one in a morphin addict, one with uremia, and one with pulmonary embolus The advantages are the absence of anaphylaxis, and the avoidance of waiting to type the sputum The drawback is the extremely sharp reaction

Comparative Study of Treatment of Lobar Pneumonia With and Without Antibody Solution

DRS R L CECIL and N P LARSEN, New York One thousand cases of pneumonia were studied bacteriologically

importance in producing right ventricle dilatation Among 213 patients without sepsis in pneumonia who were not treated by the early routine administration of a standardized tincture of digitalis the percentage of deaths believed to have been associated with cardiac failure was 25 8 Among 709 patients without sepsis in pneumonia who were treated by the early routine administration of a standardized tincture of digitalis the percentage of deaths believed to have been associated with cardiac failure was 10 7

Lumbar Puncture Cures Diabetes Insipidus—In the case reported by Tucker there was a sudden onset of diabetes insipidus without any immediate preceding illness The subjective symptoms were a sense of discomfort behind the glabella increased thirst, a disquieting volume in urine output and marked sweating of the body and extremities Physical examination confirmed the subjective symptoms, and in addition, revealed involvement of the first (?) second, fifth and eighth cranial nerves on the left side Within twenty-four hours after lumbar puncture the great thirst was relieved, the urinary output was reduced to normal and the sweating ceased Examination five and a half months after the onset of the diabetes insipidus gave negative findings *with the exception of laboratory evidence for hypopituitarism*, revealed by the very high sugar tolerance It is suggested that the disturbance was due to a serous meningitis with edema of the infundibulum cerebri and involvement of certain cranial nerves on the left side The removal of 8 cc of subarachnoid fluid even though this was under normal pressure, was adequate to restore proper circulatory equilibrium

Influenzal Meningitis—The clinical picture in this case was that of an acute meningeal infection with a positive Kernig, Brudzinski, neck rigidity, retraction of the head fever and leukocytosis The exact diagnosis was of necessity made through the bacteriologic findings in the laboratory The bacillus obtained was gram-negative, hemoglobinophilic, pleomorphic, aerobic, nonhemolytic and nonmotile In a guinea-pig intraperitoneal injection was followed by peritonitis, septicemia and death in twenty-six hours In its morphologic and cultural characteristics the organism so described corresponds with forms isolated from meningitis cases by Slawyk, Wollstein and others

Primary Carcinoma of Liver with Lung and Kidney Metastases—A case of primary carcinoma of the right lobe of the liver, originating from the epithelium of the intrahepatic bile ducts, is reported by McKean Metastases were demonstrated in the liver substance, in glands at the lung hila, in the kidney and seeded throughout the parenchyma, pleurae and blood vessels of both lungs Numerous thrombi were found in the hepatic veins Many of the classical features of tumors of this type, i e, the right upper abdominal quadrant pain, jaundice, ascites and edema, were lacking The pulmonary symptoms, thoracic pain dyspnea and hemoptysis dominated the picture throughout, producing the most interesting phase of the case, the marked reduction in vital capacity as compared with the relative insignificance of the pulmonary signs The change in vital capacity furnished the first real evidence of the extent of progress of the intrathoracic process, which was later demonstrated in the necropsy room

Diffuse Adenomyoma of Uterus—The study made by Schwarz and McNalley of forty-nine cases of diffuse adenomyoma of the uterus shows that in almost every instance this condition is present coincidently with one or more other lesions which are fundamental in influencing the development of the adenomyoma The inflammation in the uterine cases is a definite factor in the production of the lesion as in the cases of tubal adenomyoma cannot be substantiated

Neoplasia of Kidney—Davis reports five primary cases (1) papillary epithelioma, (2) hypernephroma, (3) malignant teratoma, (4) squamous cell carcinoma, (5) lymphoblastoma

Management of Cord Stump—The technic employed by Willson in the management of the cord stump and navel appeals to him as being based on sound physiologic principles When the respiratory function has been normally established and pulsation in the cord has ceased or become limited to the fetal end, traction is made on the cord perpendicularly to the body surface, in order to draw the skin cuff out to its full extent, and, after painting with 50 per cent tincture of iodin, a clamp is placed immediately adjacent to the skin margin and locked in place Care is exercised to avoid catching the skin edge in the bite of the forceps The cord is then cut through as close to the distal side of the forceps as possible and a few turns of a sterile gauze bandage are thrown around the clamp and stump in the ordinary figure of eight applications After having been left in place for one hour the clamp is gently and carefully removed by the nurse At this time the cord stump is represented by a narrow zone of congested cord tissue about one-eighth inch in thickness, surmounted by a transversely compressed translucent zone of paper thickness, the width of the jaws of the clamp The stump is again touched with 50 per cent tincture of iodin and covered with a dressing of sterile gauze, held in place by a binder Unless soiled this is not disturbed until the fourth or fifth day The baby is not tubbed Twenty-four hours after birth inspection of the navel discloses the remnant of the cord as a small dry scab which separates and comes away when the dressing is changed on the fourth or fifth day

Lutein Solution to Control Vomiting of Pregnancy—Coffey endorses the hypodermic injection of lutein in the treatment of the vomiting of pregnancy Of sixty-two cases so treated fifty-five, or 88 6 per cent were improved The earlier the injections are begun the more gratifying the results The drug is apparently harmless, easily administered and leaves no unpleasant after effects There seems to be no increased tendency to abortion if the patient remains quiet following the injections

Primary Carcinoma of Bladder—Stone reports a case in which early excision of a supposedly malignant bladder tumor by combined vaginal and abdominal operation, has resulted in an apparent cure

and clinically Half were treated with antibody solution, and half were used as controls The injection was usually followed by definite improvement and relief of pain It is difficult to estimate the therapeutic value of this agent The reactions were severe, and in three cases probably caused death In favorable cases it appears to shorten the disease and eliminate complications

Experimental Botulism, with Special Reference to Serum Therapy

DR M J ROSENAU, Boston Experiments have been worked out with the idea of procuring drugs to prevent the absorption of botulinus toxin and thus saving the patient until such time as the antitoxin can be procured Ether prevented the absorption of toxin until antitoxin could be procured Morphin had the same effect

Hemoglobinuria in Hemolytic Jaundice and Pernicious Anemia

DR H Z GIFFIN, Rochester, Minn In a case of hemolytic jaundice there occurred seven severe crises with hemoglobinuria Syphilis was excluded Cold and exposure did not produce attacks Hemoglobinuria recurred whenever the red cell count reached approximately 2 500 000 cells Three similar cases were found in the literature

Terminals of Human Bronchiole—The material used by Willson in this study consisted of portions of the lungs of two subjects obtained at necropsies performed soon after death One was a woman aged 30, who had died of mitral stenosis, while the other was a child whose age could not be ascertained definitely, but was certainly less than 13 Serial sections and wax reconstructions were studied and as a result Willson is convinced that in the branching of the respiratory bronchioles there is far greater complexity, irregularity and a greater degree of interlocking than is usually described There is no spherical space, or 'atrium,' such as has been described by Miller The method of branching of the bronchioles is dichotomous until the terminals are approached, and then the branching becomes irregular Counting as the first branch a respiratory bronchiole arising from a nonrespiratory one, the air sac is usually reached from the fifth to the seventh branch There are normally no direct communications between adjacent alveoli The bronchioles do not decrease in diameter as the periphery is approached, but remain of fairly uniform size until the air sacs are reached, and the air sacs are, as a rule, of greater diameter than the tubes from which they arise Waters' rule that the planes of successive dichotomies cut one another at right angles is only exceptionally confirmed The lung of the child is just as complex in structure as that of the adult It is calculated that during ordinary deep inspiration the total area of respiratory and nonrespiratory epithelium in the adult lung is not greater than 70 square meters

Prevention of Goiter—Kimball urges that the prevention of goiter in the adolescent period should be a public health measure under state, county or municipal control The existing systems of organization of the schools, both public and private, are sufficient to handle all the details without additional aid or expense Education of the pupils could be combined with the actual administration of iodin, so that after leaving school they could continue the treatment if necessary In industrial medicine physicians could render an important service in this direction As thyroid enlargement is approximately six times as frequent in girls as in boys, each community must decide whether it will include both sexes in prophylactic measures, as it must also decide regarding the ages when the use of iodin should begin and end In this climate probably the maximum of prevention coupled with the minimum of effort, would be obtained by the administration of iodin between the ages of 11 and 17 years As applied to schools this would mean beginning with the fifth grade

Physical Signs Suggesting Aortic Defects—In the examination of large bodies of men Craig urges that more attention should be directed to the study of the upper anterior chest than is usually devoted to this region especially, but by no means exclusively, in those over 40 In a study of 5,706 men with an average age of from 45 to 49 years, signs were found suggesting changes in the aorta in about 0 85 per cent The large proportion of cases were associated with some degree of hypertension Nonsyphilitic cases are encountered with relative frequency in which the physical signs strongly suggest the presence of aortic changes which may or may not be appreciable by roentgen-ray examination

Heart Muscle Changes in Pneumonia—An analysis was made by Stone of the data secured by the study of 1,205 patients with lobar and bronchopneumonia with reference to the digitalis therapy Two hundred and seventy-nine patients with pneumonia did not receive routine digitalis therapy while 926 patients received full dosage of a potent tincture standardized by the cat method of Hatcher The gross heart muscle changes as shown in 259 pneumonia necropsies are described, together with the microscopic study of seventy-one heart muscle sections The influence of these changes on the probable cause of death is discussed together with the benefit believed to have been secured in treatment by the use of digitalis Sepsis in pneumonia was the most serious complication and the most frequent cause of death in the subacute or chronic forms of the disease, that is, among those who died as late as the fourteenth day of illness or subsequently Among 283 patients in whom sepsis occurred there were 161 deaths, a mortality rate of 56 8 per cent, while among 922 pneumonia patients without sepsis there were 131 deaths, a mortality rate of 14 2 per cent Among the causes other than sepsis responsible for death in many acute forms of the disease, cardiac muscle failure appeared to have been a prominent factor Right ventricle dilatation was found to have occurred in 39 4 per cent of eighty-nine lobar pneumonia necropsies and in 36 6 per cent of 112 bronchopneumonia necropsies Parenchymatous, fatty and hyaline degeneration or evidence of inflammatory reaction in the heart muscle were found in 79 3 per cent of the sections from thirty-four lobar pneumonia necropsies and in 59 4 per cent of the sections from thirty-seven bronchopneumonia necropsies The extent of these changes when considered with the right ventricle dilatation was believed in many instances to have been responsible for the circulatory failure which had occurred The mechanical obstruction to the pulmonary circulation in extensive or massive consolidation was apparently a factor of great

importance in producing right ventricle dilatation Among 213 patients without sepsis in pneumonia who were not treated by the early routine administration of a standardized tincture of digitalis the percentage of deaths believed to have been associated with cardiac failure was 25 8 Among 709 patients without sepsis in pneumonia who were treated by the early routine administration of a standardized tincture of digitalis the percentage of deaths believed to have been associated with cardiac failure was 10 7

Lumbar Puncture Cures Diabetes Insipidus—In the case reported by Tucker there was a sudden onset of diabetes insipidus without any immediate preceding illness The subjective symptoms were a sense of discomfort behind the glabella increased thirst, a disquieting volume in urine output and marked sweating of the body and extremities Physical examination confirmed the subjective symptoms, and in addition, revealed involvement of the first (?), second, fifth and eighth cranial nerves on the left side Within twenty-four hours after lumbar puncture the great thirst was relieved, the urinary output was reduced to normal and the sweating ceased Examination five and a half months after the onset of the diabetes insipidus gave negative findings with the exception of laboratory evidence for hypopituitarism revealed by the very high sugar tolerance It is suggested that the disturbance was due to a serous meningitis with edema of the infundibulum cerebri and involvement of certain cranial nerves on the left side The removal of 8 c.c of subarachnoid fluid, even though this was under normal pressure, was adequate to restore proper circulatory equilibrium

Influenzal Meningitis—The clinical picture in this case was that of an acute meningeal infection with a positive Kernig, Brudzinski neck rigidity, retraction of the head, fever and leukocytosis The exact diagnosis was of necessity made through the bacteriologic findings in the laboratory The bacillus obtained was gram-negative, hemoglobinophilic, pleomorphic, aerobic, nonhemolytic and nonmotile In a guinea-pig intraperitoneal injection was followed by peritonitis, septicemia and death in twenty-six hours In its morphologic and cultural characteristics the organism so described corresponds with forms isolated from meningitis cases by Slawyk, Wollstein and others

Primary Carcinoma of Liver with Lung and Kidney Metastases—A case of primary carcinoma of the right lobe of the liver, originating from the epithelium of the intrahepatic bile ducts, is reported by McKean Metastases were demonstrated in the liver substance, in glands at the lung hila in the kidney and seeded throughout the parenchyma, pleurae and blood vessels of both lungs Numerous thrombi were found in the hepatic veins Many of the classical features of tumors of this type, i e, the right upper abdominal quadrant pain, jaundice, ascites and edema, were lacking The pulmonary symptoms, thoracic pain, dyspnea and hemoptysis dominated the picture throughout, producing the most interesting phase of the case, the marked reduction in vital capacity as compared with the relative insignificance of the pulmonary signs The change in vital capacity furnished the first real evidence of the extent of progress of the intrathoracic process, which was later demonstrated in the necropsy room

Diffuse Adenomyoma of Uterus—The study made by Schwarz and McNalley of forty-nine cases of diffuse adenomyoma of the uterus shows that in almost every instance this condition is present coincidently with one or more other lesions which are fundamental in influencing the development of the adenomyoma The inflammation in the uterine cases is a definite factor in the production of the lesion as in the cases of tubal adenomyoma cannot be substantiated

Neoplasia of Kidney—Davis reports five primary cases (1) papillary epithelioma, (2) hypernephroma, (3) malignant teratoma (4) squamous cell carcinoma, (5) lymphoblastoma

Management of Cord Stump—The technic employed by Willson in the management of the cord stump and navel appeals to him as being based on sound physiologic principles When the respiratory function has been normally established and pulsation in the cord has ceased or become limited to the fetal end, traction is made on the cord perpendicularly to the body surface, in order to draw the skin cuff out to its full extent, and after painting with 50 per cent tincture of iodin, a clamp is placed immediately adjacent to the skin margin and locked in place Care is exercised to avoid catching the skin edge in the bite of the forceps The cord is then cut through as close to the distal side of the forceps as possible and a few turns of a sterile gauze bandage are thrown around the clamp and stump in the ordinary figure-of-eight applications After having been left in place for one hour the clamp is gently and carefully removed by the nurse At this time the cord stump is represented by a narrow zone of congested cord tissue about one-eighth inch in thickness, surmounted by a transversely compressed translucent zone of paper thickness, the width of the jaws of the clamp The stump is again touched with 50 per cent tincture of iodin and covered with a dressing of sterile gauze, held in place by a binder Unless soiled this is not disturbed until the fourth or fifth day The baby is not tubbed Twenty-four hours after birth inspection of the navel discloses the remnant of the cord as a small, dry scab which separates and comes away when the dressing is changed on the fourth or fifth day

Lutein Solution to Control Vomiting of Pregnancy—Coffey endorses the hypodermic injection of lutein in the treatment of the vomiting of pregnancy Of sixty-two cases so treated fifty-five, or 88 6 per cent were improved The earlier the injections are begun the more gratifying the results The drug is apparently harmless, easily administered and leaves no unpleasant after effects There seems to be no increased tendency to abortion if the patient remains quiet following the injections

Primary Carcinoma of Bladder—Stone reports a case in which early excision of a supposedly malignant bladder tumor by combined vaginal and abdominal operation, has resulted in an apparent cure

Report of Case of Epidemic Encephalitis with Cord Changes Suggestive of Possibility of Early Syringomyelia A F Harris, Worcester Mass —p 679

Precipitating Situation of Manic Depressive Psychosis and Dementia Praecox—Strecker's study embraces a comparison between 100 manic-depressive psychoses and 100 cases of dementia praecox from the standpoint of the significance of the precipitating situations and a further comparison as to whether the organic or the psychogenic aspects were more emphatic A significant or important precipitating situation occurred in fifty-two, or more than 25 per cent, of the patients Influenza, overwork and exhaustion, the climacteric and complicated childbirth, were the most frequent somatic factors, the most common psychic problems were cruelty, poverty, illness and death of relatives, and unhappy love affairs Significant and important exciting factors were more frequent by 12 per cent in manic depressive psychosis, there was little difference between the two forms of mental disease in the doubtful and insignificant groups, but the absence of favoring circumstances was six times more frequent in schizophrenia The proportion of somatic and psychic features was practically the same for manic depressive and dementia praecox, the somatic predominating in the significant and important situations, the psychic in the doubtful and insignificant ones An abnormal personality occurred with greater frequency in those patients whose mental illness came on without adequate exciting factors The percentage difference was 13 per cent for manic depressive psychosis and 24 per cent for schizophrenia

Heredity in Epilepsy—In view of past experience and present knowledge, Thom and Walter are quite convinced that epilepsy, as such, does not exist and is by no means entitled to the classification of a disease entity The syndrome which goes to make up the condition which has borne the name of epilepsy is neither constant nor characteristic The convulsions caused by lesions of the kidney are quite indistinguishable from those produced by an acute infection In neither case, may they differ from the group called idiopathic epilepsy An extremely high percentage of the cases which come to necropsy have gross brain lesions and many of these cases during life have been diagnosed as idiopathic epilepsy One hundred and seventeen cases were selected for review The diagnosis of epilepsy had been determined in all these cases The subjects had all been married and had borne one or more living children The total number of children resulting from these 117 matings was 431, of which 280 are still living Of the parents seventy-six were females, forty-one males Ninety-nine cases were idiopathic, eighteen organic The onset of the convulsions began in fifty-nine cases prior to marriage and in fifty-eight cases after marriage Of the total of 117 epileptic parents only twenty-two gave birth to epileptic children Thom and Walker believe that epilepsy as a disease is not transmitted directly from parent to offspring, but rather that it is the nervous system lacking in the normal stability that is inherited, and the manifestations of this instability may be mental deficiency of all degrees, insanity of various types, neurologic and psychopathic disorders convulsions from various exciting causes which would have little or no effect on a normally developed nervous system These mental and nervous disorders are less frequently found in the offspring of the so-called epileptic than has heretofore been believed and the future of the offspring borne of epileptic parents is not as hopeless as the pessimistic authorities on heredity record Maternal defects are more frequently manifested in some form or other in the offspring than are the paternal defects and, when present, are more likely to appear at an earlier age

Gastrin Theory Put to Physiologic Test A C Ivy and J E Whitlow, Chicago —p 578

Experimental Traumatic Shock—In six out of nine cases reported by Rapport there is evidence of hyperactivity of the suprarenal glands during the development of traumatic shock There is no sufficient reason to believe that either oversecretion of the suprarenals, or their exhaustion, is a factor in the production of shock The probability is suggested that overactivity of the glands is a conserving factor in the development of shock

Effect of Breathing on Blood Pressure—The effects of rapid breathing were compared by Trotter et al with those of more normal breathing upon the systolic blood pressure in man Supplementary data were also obtained on the dog and cat For the well known changes of blood pressure that occur during a single respiration, and which are more or less synchronous with the changing respiratory phases, the authors have proposed the name of simple cardiorespiratory waves to distinguish them from those waves produced by rapid breathing The oscillations of pressure elicited during rapid breathing by the interference method they have designated as cardiorespiratory interference waves The most striking difference in the respiratory relations of the simple and interference waves is that in the simple waves the blood pressure changes are complete within the period of a single respiration, while in the interference waves the gamut of the blood pressure changes is run through in the interval of several respirations The production of interference waves of blood pressure is dependent on the establishment of cardiorespiratory cycles, in which the number of respirations is greater by one or less by one than the number of heart beats making up the waves and occurring in the same time interval

Ammonia Production in Nerve Fiber—Evidence is given by Tashiro to show that resting nerves give off exceedingly minute quantities of a volatile base-forming substance which

during stimulation is greatly increased and that this substance is probably ammonia Methods are described by which as little as 0 00000001 gm ammonia can be measured

Substance in Urine with Properties of Citric Acid—The substance isolated by Amberg and Mayer from urine in the form of an impure barium compound had certain properties in common with citric acid These results support a previously made contention that citric acid occurs in the urine of normal human beings, but still they do not convey absolute proof, which rests solely on the isolation of the acid or its salts in a form pure enough for identification

Influence of Meat on Physical Efficiency—The results obtained by Bassett et al show that the presence or absence of meat from the dietary, during periods as long as one week, has no demonstrable effect on the capacity of doing an amount of work so graded as to reach the limit of the physical capacity during a short period of time This accords with the doctrine of Chittenden There was a distinct and uniformly present sense of sleepiness for two or three hours during the afternoon period following the ingestion of 300 gm meat Removal of meat from the dietary for a period of one week did not diminish the sense of well being in the persons investigated The well nigh universal opinion that meat ingestion is important for the maintenance of physical strength is not to be disregarded, but the experimental evidence in favor of this conception has yet to be produced

Epidemic Encephalitis with Myelitis W G Spiller Philadelphia—p 739
*Actinomycosis of Central Nervous System F P Moersch Rochester Minn—p 745

Study of Parkinson's Disease—One hundred and forty-six private cases of 'classical' paralysis agitans were used by Patrick and Levy for studies in age and sex distribution, 140 for clinical studies Frequency by decades was found to be greatest in the fifties and next in the forties 80 per cent of the patients were between 40 and 70 and 55 per cent were over 50 years of age These findings agree with other statistics Considered in relation to the age incidence of the general population, the vast majority of patients are over 50 when the disease begins, and the onset is relatively more frequent in the seventies than in the thirties The ratio of males to females was 3 to 2 Trauma occurred in twenty-two cases, and in these as in the histories of infected parts it was shown that the symptoms of paralysis agitans tend to start in a traumatized or diseased part Since in this series there was a history of trauma in only 15 per cent of all cases, it cannot be concluded that trauma is predisposing in any sense except as to the site of the initial symptom A large number of mental symptoms were shown by forty-eight patients, or in 34 per cent of the cases In contrast with the findings in other studies, *mental symptoms* were found to occur as frequently before as after the onset of the disease These symptoms were largely in the form of depressive reaction Menstrual disturbances were found to be of no special significance Heredity findings were not significant except in the form of 'neuropathic heredity" in about 25 per cent of the cases Direct heredity of the disease was traced in six cases The complications were tabes, one, hemiplegia two, trifacial neuralgia, two, hyperthyroidism, one, and diabetes one Fifteen patients had hemiparalysis agitans, eighteen cases were accompanied by intention tremor five patients had one-sided facial involvement four had paralysis agitans sine agitatione, two paralysis agitans sine rigiditate and three had "bulbar symptoms"

Heredity in Epilepsy—Burr's statistics do not show that direct inheritance is important since only thirty-four parents were known to be affected On the other hand the frequency of insanity, crime, chorea, alcoholism and epilepsy in relatives points toward congenital instability resulting from abnormality in the germ cell or sperm cell Considering all the data, it is safe to assume, Burr says, that the effect of heredity is rarely direct, that usually it is indirect and general not specific In other words, a predisposition to nervous or mental disease is inherited, the resulting specific disease depends on external causes—it is environmental in the broadest meaning of the word

Intravenous Administration of Iodids—Recognizing the value of intravenous hypertonic iodids in the treatment of oidiomycosis at least 400 intravenous injections of hypertonic iodids have been given by Farnell and observations have been made on the value of this iodid therapy He has used sodium iodid exclusively *The preparation is made in from 8 to 15* per cent (10 per cent is the usual rate) solutions in distilled water which is also autoclaved—amount, 100 c c This is then boiled and cooled and given by gravity intravenously (made fresh for each treatment) A distinctly hypertonic solution of high concentration is thus produced In no case has there been any irritation of the digestive tract Skin eruptions were observed in one case Coryza was observed in one case Farnell is convinced that iodin injected into the blood stream in hypertonic form has a tendency to reduce the idiosyncrasy toward iodism Iodids introduced into the blood stream appear to readjust systemic fungus disturbances (oidiomycosis) very rapidly Iodids injected intravenously in concentrated form appear to help materially the action of arsphenamin on the diseased tissues and cells Iodids introduced into the blood stream in hypertonic solutions probably have some influence on reducing the edema, hyperemia, etc, of the brain in increased brain bulk disorders

Serology of Neurosyphilis During Nontreatment Period—A selected group of nine paretic patients was studied by Omar and Carroll during a period of over six months, during which time no specific medication was administered Eight of the nine gave findings which were uniformly positive in both the blood and cerebrospinal fluid The laboratory findings remained practically unchanged during a seven month period of nontreatment

Actinomycosis of Central Nervous System.—Moersch presents the clinical history of two cases which terminated fatally and in which the necropsy showed extension of the disease to the membranes of the brain and cord and in one case the brain substance showed some cell degeneration and slight blood vessel infiltration and the *cord substance showed* some swelling of the nerve cells with displaced nuclei and moderate blood vessel infiltration but no abscesses or foci were discovered and no fungi were found in the membranes of the cord

*Dispensary Development with Especial Reference to Outpatient Department of Massachusetts General Hospital P D White Boston—p 693
*Acute Intussusception W F Harper Boston—p 700
*Experience with Radium in Malignant Disease of Esophagus and Upper Respiratory Tract H H Forbes New York—p 705

Acute Intussusception—In the cases reported by Harper from the Children's Hospital, the following symptoms were present in the following order (1) Recurring attacks of pain associated with pallor, cold sweat and reflex nausea (2) Mucus blood stained mucus, and blood in movements (3) Obstructive vomiting (4) Toxemia due to obstruction In 112 cases there were forty-four deaths, a percentage death rate of 39 2 The mortality depends less on the skill of the operator than on the length of history prior to operation Therefore, it lies in the hands of the practitioner to reduce the mortality

Radium Therapy of Esophagus Cancer—Forbes states that the results of the use of radium in cases of esophageal cancer have been nil In the pharyngeal and the laryngeal cases of cancer the results are not quite so bad The earliest recognition of malignancy in the larynx and early operation will give the greatest benefit to the patient Radium may be applied before the operation or later Forbes does not feel that radium is a powerful therapeutic agent Cooperation must exist between the radiologist and the specialist, both for diagnosis and for treatment Failures of today may be successes of tomorrow, as knowledge of the more scientific application of this element increases

*Avulsion of Scalp Review of Literature and Report of Case C A Porter and W M Shedden Boston—p 727
*Traumatic Osteitis of Wrist M H Rogers Boston—p 730
*Transperitoneal Cervical Cesarean Section Report of Cases L F Phaneuf and J G Hegarty Boston—p 733
*Glioma of Lumbar Cord Case Report D S Adams Worcester Mass—p 738

Avulsion of Scalp—Porter and Shedden relate the case of a woman aged 58, who was caught by the hair in the revolving wheel of a shoe-stitching machine and her entire scalp was torn off, as was also the upper part of both upper lids and the left ear, excepting the tragus, antitragus and lobule This left upper ear remained attached by a narrow pedicle posteriorly After nine weeks of wet dressings a heterogenous Thiersch graft was transplanted to the patient's vertex This did not take Reverdin autogenous grafts were then applied This procedure was repeated about every ten days during the next three months, and most of these grafts took It was noted during the time she was under observation that the scalp tended to intermittently lose considerable portions of skin from pressure or microbic invasion The patient complained of a constant dull ache in her "eyeballs" An attempt was made to get better vascularization of the scalp by drilling through the calvarium to the dura through five of the ulcerated areas in the front region She improved slightly for a while as regards the ulcerations, but entered the hospital again six months later, showing six large and ten small ulcerations She now complained of a constant dull generalized headache and of a feeling of pressure so intense that she could not even bear to have her wig one Eighteen holes about 1 cm in diameter were drilled through the calvarium to the dura One week after operation the headache had disappeared From that time the scalp gradually healed Each drill hole continued to suppurate until it discharged a bit of necrotic bone, the necrosis resulting from the trauma of the drill used in the trephining These pieces were sometimes complete bony rings The patient now feels perfectly well The scalp is almost completely healed and shows no tendency to break down

Traumatic Osteitis of Wrist—Rogers reports four cases in which there was an absorption of the bone structure of the scaphoid or the semilunar with a 'crinkled" appearance of the contour probably secondary to trauma

Transperitoneal Cervical Cesarean Section—Of thirty-three transperitoneal operations analyzed by Phaneuf and Hegarty there were nine septic, twenty-one clean cases, and three deaths The puerperium in the clean cases was as near ideal as it can be following an abdominal section These patients were free from peritoneal shock and paralytic ileus, and the bowels, as well as the bladder, functioned normally The convalescence, as a whole, resembled more closely that of a normal delivery than that of a cesarean section The authors state that the transperitoneal cesarean section seems to afford protection against septic peritonitis There is less shock as the intestines are not handled There is less bleeding The mother has a much easier puerperium There is better healing since the incision is in the cervix, the noncontractile part of the uterus There is less danger of rupture in subsequent pregnancies It does not contraindicate the test of labor

Glioma of Lumbar Cord—The case cited by Adams is of interest because, although a fatality, it was complete The neoplasm was irremovable Involving the cord from the second lumbar segment down, it invaded the anterior horns, giving chiefly motor symptoms The posterior horns being less involved, few sensory disturbances were elicited The fluid obtained at lumbar puncture gave an example of Froin's syndrome

Sources of Error in Epstein Method for Blood Sugar Determination and Modified Technic C M Wilhelmj St Louis—p 489
Blood Sugar Content of Capillary Blood as Compared with That of Venous Blood I Neuwirth and I S Kleiner—p 495

Estimation of Blood Flow—From a large number of blood flow determinations on normal persons Taylor found that the amplitude of the flow differs widely in different persons, that the flow fluctuates spontaneously to the extent of several grams per 100 c c per minute in the same individual *during the course of an experiment*, and that marked alterations in the flow are effected by changes in the temperature of the atmosphere The flow in the hand may be influenced reflexly by applications of heat or cold to either hand or foot Thus immersion of the hand in hot or cold water produces a rise or fall respectively in both hands The response to draughts is similar in nature to the response following the immersion of the hand in cold water Heat applied to the feet produces in some individuals a rise and in others a fall in the blood flow through the hands, the particular effect produced is constant for the same individuals Local exercise produces a drop in flow of the opposite hand The flow in the exercised hand is increased in some cases and reduced in others, the effect being unpredictable

Extract of Fetal Pancreas—The possibility that the fetal pancreas might prove a source of an extract rich in internal secretion and yet free from the destructive enzymes of pancreatic juice led Banting and Best to experiment with fetal calf pancreas By intravenous and subcutaneous injections of neutral saline extracts prepared from the pancreas of the bovine fetus at about the fifth month, the percentage of blood sugar and the daily urinary excretion of sugar were markedly reduced in depancreated dogs Daily injections of extract of pancreas enabled a depancreatized dog to live for seventy days The active (antidiabetic) principle of such extracts is destroyed by boiling in strongly acid reaction, but it is not affected by the presence of tricresol, which may, therefore, be used as a preservative The depressor action of the extract is shortlived

Yeast Does Not Increase Uric Acid Excretion—The data obtained by Smith et al show that the ingestion of therapeutic doses of live bakery yeast is not attended with such an increase in metabolism as would augment the excretion of endogenous uric acid

Blood Sugar Content—In twenty individuals the capillary blood sugar was found by Neuwirth and Kleiner to closely parallel the venous blood sugar For clinical purposes the two values may be considered identical

Symptomless Hematuria—Of 100 cases of symptomless hematuria investigated by Burgess the hematuria was of vesical origin in 65 cases, villous papilloma, 41 cases; malignant growth 18 cases, enlargement of prostate 3 cases, ulceration from suture left after colporrhaphy, simple "solitary" or "mucous" ulcer calculus fixed in postprostatic pouch, one case each The hematuria was of renal origin in 35 cases bleeding not seen at the time of examination, cause unknown, 14 cases, malignant growths (including hypernephroma) 9 cases, papilloma of the renal pelvis, 2 cases, angioma of renal papilla, 1 case, renal calculus, 3 cases congenital cystic disease, 1 case, chronic nephritis, with small cysts 1 case, mobile kidney, 2 cases, "essential" hematuria 2 cases Burgess emphasizes the great importance when called to a case of symptomless hematuria, of treating the patient rather than the hemorrhage, and of not attempting to arrest the bleeding until, by means of cystoscopy, it has been traced to its source

Treatment of Vomiting of Pregnancy—Oldfield claims that vomiting of pregnancy can be cured quickly, as a rule, and with a high degree of certainty by the removal of the patient to a hospital or nursing home and by feeding on ordinary diet Induction of abortion is seldom or never necessary The so-called toxemic cases are usually, if not always, a later stage of neurotic vomiting

Parathyroid Treatment of Calcium Deficiencies—*Though* the cases described by Grove and Vines are representative of a variety of conditions they were all due to some chronic toxic state, and all had a deficiency in the ionic calcium of the serum due, perhaps, to a combination of calcium and toxin In the majority of cases it was possible to find a primary septic focus, and sometimes the administration of parathyroid caused a hidden focus to become apparent by increasing the leukocytic reaction to the attacking organism An examination of the literature tends to establish the proposition that the parathyroid glands have a double function first, a regulation of calcium metabolism, and secondly, the power to render a certain toxic substance harmless Further, it may be noted that in animals whose parathyroid function has been interfered with, either by removal or ligation of the glands, if tetany does not supervene shortly and so cause death, there is a very strong tendency for the animals to die from an infective process It is possible that the continued absorption of toxic substances from some primary septic focus may eventually lead to partial parathyroid insufficiency and a disturbance of calcium metabolism

These two conditions will cause a decrease in the resistance of the tissues, so that they are rendered more liable to a secondary septic process The locality of the latter lesion will depend on local conditions of nutrition, blood supply and so forth

*Complement Fixation Reaction in Tuberculosis A N Smith—p 212

Complement Fixation Reaction in Tuberculosis—The position as regards the value of the complement fixation test as a diagnostic procedure in tuberculosis is summed up by Smith as follows In a clinically suspicious case, when the Wassermann is negative, a positive complement fixation reaction is strong presumptive evidence of tuberculosis In a clinically tuberculous patient a positive reaction denotes activity of the lesion Repeated negative reactions may be taken to indicate either the absence of tuberculosis or that a lesion previously active has become inactive A single negative is of little or no value in a clinically suspicious case The reaction may be negative in far advanced cases in which death is imminent A positive reaction is most likely to be found when the presence of tubercle bacilli in the sputum, or the clinical signs and symptoms render the test unnecessary for diagnosis Nonspecific fixations may occur, notably when the serum gives a positive Wassermann reaction The intensity of the reaction seems to bear no relation to the patient's power of resistance or to the degree of severity of the infection

Rôle of Human and Bovine Types of Tubercle Bacilli—The role of human and bovine types of tubercle bacilli in various kinds of human tuberculosis in England and other countries was investigated by Corbett and he found that in the pulmonary and bronchial gland cases the proportion of bovine infections is negligible—little more than 1 per cent in primary pulmonary tuberculosis, and in bronchial gland tuberculosis out of seventeen cases examined only one yielded bovine bacilli—a case with no visible tuberculosis in these glands or elsewhere In the group, including abdominal tuberculosis and tuberculosis of cervical glands, the proportion of infections with tubercle bacilli of bovine type is much higher —in round numbers, 50 per cent at all ages From these facts several inferences are drawn by Corbett The frequent occurrence of bovine tubercle bacilli in cervical glands and their rarity in bronchial glands is strongly opposed to the view that tubercle bacillus tracks downward from gland to gland extending in this way from the neck to the thorax and so to the lungs In order to hold this view it would have to be assumed that only tubercle bacilli of human type can track in this way Again, the fact that bovine tubercle bacilli are so frequent in mesenteric glands and so rare in the lungs is in opposition to Calmette's view that pulmonary tuberculosis is commonly caused by tubercle bacilli, absorbed through the intestinal mucous membrane, and carried by the thoracic duct and the innominate vein to the right side of the heart, and so to the lungs If this were the common channel of infection one would expect to find the same proportion of bovine infections in pulmonary as in abdominal tuberculosis Lastly, the fact that bovine tubercle bacilli have frequently been found in abdominal and cervical tuberculosis (that is, in cases arising from infection through some part of the alimentary canal) and seldom in the lungs, is easily explained on the ground that human tubercle bacilli alone are sprayed into the air, therefore alone have a chance of entering the lungs directly, while bovine tubercle bacilli, being limited to food substances, can only infect man through the alimentary canal The inhalation theory of the origin of pulmonary tuberculosis thus receives strong support In cases of general tuberculosis, meningitis, tuberculosis of bones and joints, and genito-urinary tuberculosis, the proportion of cases in which bovine bacilli have been found is nearly the same Probably both aerial and food infections contribute to this group in the same proportion as they occur in the form of primary infections Twenty per cent of bovine infections may, therefore seem high for these blood borne infections, but the majority of these cases occur in early life when infections through the abdominal route with its large proportion of bovine bacilli are far commoner than they are later In lupus the proportion of bovine infections was 50 per cent of the deaths attributed to tuberculosis of all kinds, about 6 5 per cent are attributable to bovine bacilli, and therefore to infection coming from the cow, probably in the immense majority of cases through milk

Intermittent Complete Heart Block—The case recorded by Wells and Wiltshire shows how remarkably chronic and latent and infective nonsyphilitic endocarditis can be During the twelve years the patient was under frequent observation sometimes with complete block, sometimes free from block, he was never actually found to be in the transitional stage of partial block Considerable variation in the pulse rate was found at different times but irregularity was never noted subsequent to the occasion when he first sought medical advice about his heart thirteen years before death Further, the ventricular rates observed at times when complete block was present are noteworthy Two electrocardiograms taken in 1915 show ventricular rates of 51 and 49 per minute, respectively with complete block In 1920, after auricular fibrillation had set in three electrocardiograms show ventricular rates of 60 per minute, although the perfect regularity of the ventricle proves that all impulses from the auricle were completely blocked, and the clinical records at this time show that an average ventricular rate of 73 per minute was maintained for three weeks, a maximum of 88 being attained on three occasions These rates are so high for an idioventricular rhythm that they compel speculation concerning the site of origin of the stimuli to which the ventricle was responding It was conjectured, during life that the lesion must have produced functional section of the conducting tissues across the A-V node, leaving sufficient intact nodal tissue below it to serve as the pacemaker to the ventricle Postmortem the changes in the conducting tissues were found to be diffuse, and no particular level can be selected as the most severely affected The A-V node and bundle lying as they did quite at the periphery of the main septal inflammatory focus, have suffered very much less than the tissue immediately subjacent to them Their conducting function must have been interfered with in two ways—namely, (1) by transmitted pressure due to inflammatory tension in the underlying focus, and (2) by direct implication in the inflammatory process Of these two factors the authors think that transmitted pressure was the more important in producing the clinical events of the case

Bundle Branch Lesions—From about 500 consecutive patients a frequency of 1 6 per cent is given by Bishop for this lesion Some patients had a very definite history of severe attacks of pain, lasting several hours, followed by gradual recovery, in others the onset of pain did not appear so clearly in the history The records of these eight people fall into two groups In the first group of four cases the records show the typical characteristics necessary to diagnose a disease of one bundle branch which completely destroys the function The *R* waves or *S* waves are large and wide and show notches, and the *T* waves are large and

downward in Lead 1 The four remaining records are not so typical of this condition However, they all show marked abnormality in the notching or in the width of the *R* waves so that the lesion must be considered a serious one, if not complete The four patients with typical records complained of severe pain over the heart, and also showed greatly increased blood pressure In the other four there was no increase in blood pressure of any extent, and there was a history of pain in only one person The orthodiagrams of the hearts of those with typical records all revealed markedly enlarged hearts of the aortic type Only two of the patients with less typical histories showed this enlargement, the other two having enlarged hearts of the vertical type There was no uniformity in duration of disease, one man having a normal tracing two and a half years prior to the appearance of a typical bundle branch lesion Dyspnea and precordial pain were present in each record, the precordial pain being most marked in those with definite bundle branch tracings These attacks, which were intermittent, came on usually by exertion In one person it was the chief complaint which brought him for examination Only two of the typical bundle branch cases were bothered with cough—brought on, no doubt, by some congestion in the lungs The heart valves were not primarily involved in one half of the patients

Treatment of Abscess—The principle of the method advocated by Kellock is this The abscess is opened at its highest point, the cavity is at intervals filled to its utmost capacity from the bottom upward with an antiseptic fluid which remains partially distending it and continually soaking the walls until they are rendered sterile In streptococcus or staphylococcus infections Kellock prefers flavine 1 1,000 It is of little or no use in cases of *Bacillus coli* infection or against the tubercle bacillus The use of flavine should also be limited in time, it will be found to delay healing if kept in contact with normal tissues more than six or seven days When the interior of the cavity has been rendered comparatively sterile, and the injection of flavine has been discontinued, it may be advisable to make a puncture in the most dependent position, and put in a small drainage tube in order that the closing up of the cavity may be as rapid as possible In the case of cysts, such as hydroceles which are lined by a single layer of endothelium, a very brief application of an irritating fluid is sufficient, if a sufficient quantity of iodin solution or phenol be introduced and withdrawn again in ten minutes it will generally be found to have accomplished its object, the treatment, however, is very painful and a general anesthetic will be necessary A previous injection of a local anesthetic is not sufficient

Wrist Watch Neuritis—Two cases are recorded by Stopford in which neuritis was caused by the band of a wrist watch making pressure on the dorsal cutaneous branch of the ulnar nerve, on the dorsal surface of the styloid process of the ulna On discarding the wristlet the discomfort gradually disappeared

Vaccine Therapy of Urticaria—The urticaria in Armstrong's case was of ten years' duration and began after having eaten a dish of mushrooms Every four or five days a red rash appeared, rapidly reached a maximum degree of intensity and extent, and usually subsided almost completely within forty-eight hours of the first onset The rash was accompanied by a temperature which often rose as high as 102.5 F, and by a considerable amount of headache and general malaise The eruption followed no definite plan of distribution, but developed on any part of the face, body, or limbs A light blow or the exertion of pressure on any part of the patient's body produced an urticarial swelling of greater or less degree according to the amount of violence exerted The patient suffered from rheumatism and from sore throat The history suggested that an organism of streptococcal type might be the cause of the trouble A catheter specimen of urine was obtained when the patient was in the middle of an attack. From this a small badly staining short streptococcus was isolated This was grown with some difficulty aerobically on trypsin agar and a vaccine prepared Its use was followed by a complete cure

Psoriasis and Pregnancy S P Impey—p 156

Syphilis and Mental Deficiency—In 217 cases of amentia Key and Pijper have, by means of the Wassermann reaction, demonstrated the presence of syphilis in 120, or 55.2 per cent They have not been successful in observing any symptom, or group of symptoms common to the cases giving a positive reaction It is their opinion that the syphilitic virus cannot alone be responsible for the amentia in all these cases The chances are that some other predisposing cause is also present in most cases

Resection of Stomach for Cardiac Ulcer—Daly narrates the case of a woman, aged 39, who had been suffering from periodical attacks of pain in the region of the stomach for six years—sometimes followed by vomiting, which usually relieved the pain The attacks came on from half to an hour after eating The abdomen was opened and an ulcer found near the cardiac orifice of the stomach extending on the anterior surface from the lesser nearly to the greater curvature, and at the upper part also onto the posterior surface of the organ A sleeve resection was done, removing the whole of the affected parts joining the cut ends in the usual way and a gastro enterostomy performed distal to the anastomosis The patient made an uneventful recovery and has been able to eat without discomfort since the operation has put on weight, and has been confined of a healthy child

May 9 1922 87 No 19

*Vaccine Therapy of Typhoid Bone Disease H Vincent—p 517
*Roentgen Epithelioma Cured by Diathermy H Bordier—p 526

Typhoid and Paratyphoid Osteopathies—Vincent has compiled thirty cases of this kind treated by vaccine therapy, and adds another convincing example of the remarkable efficacy of this treatment in certain cases His patient was a young woman who developed a series of abscesses during convalescence from what was supposed to be typhoid Various joints swelled, and there were foci of osteomyelitis in the fibula ulna and scapula and, finally, multiple foci of osteitis in the bones of the pelvis The intense pain from this had suggested psoitis, appendicitis or encapsulated peritonitis at first The blood agglutinated the paratyphoid B and under vaccine therapy the pains subsided in eight hours and all the symptoms from the osteitis rapidly disappeared, and with them those of mucomembranous enteritis The vaccine was not administered until the bone lesions had been under way for three months and the cachexia was extreme She was given four injections of vaccine in all, representing a total of 2.5 thousand millions of the bacilli Vincent advises inquiry for typhoid in all cases of bone lesions, and, if syphilis and tuberculosis can be excluded, he urges vaccine therapy without further ado Smears from the pus or secretions may disclose typhoid or paratyphoid bacilli, and vaccine therapy may prove an effectual adjuvant to surgical measures, and to specific treatment of concomitant syphilis His experimental research has demonstrated that while the blood after disease of the typhoid group may be strongly bactericidal and abound in antibodies, yet the bile and the urine are not bactericidal and do not contain ant bodies Hence the bacilli may lurk for years in the gallbladder, bladder or bone marrow and they may set up a focus of osteitis even many years later

Roentgen Cancer Cured by Diathermy—Bordier had charge of the roentgen tubes used at Lyons during the war, and in the course of nearly three years supervised 10,755 therapeutic applications of the rays Twenty epitheliomatous patches developed on his fingers, and the largest patch began to ulcerate and to pain after two or three years Amputation of the finger was advised, but he applied diathermy himself

with his other hand The severe pain was arrested immediately, and healing was complete in less than two months, and there has been no recurrence during the five or six months since

Serotherapy of Poliomyelitis R Debré —p 708

Indications for Ouabain—Ribierre reproduces some tracings which demonstrate that ouabain can be given to advantage even when there is high albuminuria and insufficiency of the kidneys, and even azotemia, if the ouabain is called for by insufficiency of the heart from lack of tone in the myocardium, especially of the left ventricle The drug has to be given tentatively and cautiously under these conditions, the subject in bed, and on a salt-poor diet He recalls that ouabain should not be given until after an interval of at least eight days after digitalis has been administered On the other hand, digitalis can follow the ouabain with favorable results, especially from the standpoint of the diuresis

Suppurating Parotitis—Weil extols the advantages of thread drainage Two silk threads are passed through the lobes of the parotid gland with a Reverdin needle The threads are drawn along each morning to start the flow of pus In one of the two cases a vaccine was made from the staphylococci on the threads

Consonance in the Mouth of Intrathoracic Sounds—Ricaldoni devotes eight pages to discussion of sounds heard in the mouth, synchronous with the pulse, or the second pulmonary sound heard at the mouth as plainly as in precordial auscultation

Bronchiectasis in Adults—De Jong and Hutinel remark that the diagnosis is almost impossible unless the sputum is collected in a graduated glass which will reveal its exceptional quantity The paroxysmal course is also instructive This has long been emphasized in bronchiectasis in children, as also the tendency to a spontaneous cure in the young In adults, bronchiectasia is generally mistaken for pulmonary tuberculosis In one case febrile hemoptysis and signs of a cavity seemed to render tuberculosis certain but during repose the symptoms subsided for a time and then returned The expectoration was like a vomica No benefit was derived from artificial pneumothorax nor an autogenous vaccine The bronchi had enlarged so generally that the parenchyma of the lung had been almost completely crowded out, and the aspect resembled that sometimes seen in still-born syphilitic children

Progressive Muscular Atrophy—The young man died eight months after the onset of the afebrile disease Inoculation of two rabbits and six guinea-pigs resulted in pseudoparetic amyotrophy, with tachycardia in one rabbit It developed six months after it had been inoculated with an emulsion of the cervical spinal cord from the clinical case

Fatal Measles—Renaud found ear and brain complications in several cases of fatal measles In three cases the grave ear disease found at necropsy had not been suspected during life In all the cases of fatal measles, the otitis was evidently entirely or partially responsible for the fatal outcome The otitis formed part of the clinical picture from the start, but *secondary purulent infection was responsible for its gravity* Grave measles is thus aggravated measles The pathology of the infectious diseases is changing from what it used to be Cleanliness, in the surgical sense of the word, usually wards off the secondary aggravation of measles, for example and the resulting disease is so mild that it does not fit the classical description of measles" On the other hand he adds, when secondary infection aggravates the case, the disease is too grave to fit the classical description

Compression of Pulmonary Artery—Laubry here reports a second case of insufficiency of the right ventricle from pressure on the pulmonary artery, in this case, from an aneurysm

Radium Treatment of Cancer of the Esophagus—A thread swallowed, always finds its way through the stenosis and into the stomach and bowel The sound containing the radium has two holes near the tip and the thread is passed through them The 6 meter thread thus serves as a guide and aid for the introduction of the radium

Journal de Médecine de Bordeaux

*Irradiation of Spleen in Tuberculosis P Mauriac —p 231
Four Cases of Othematoma L Verdelet and J Chavannaz —p 233
Paraffinoma H Lefevre A Bonnard and P Prechaud —p 234
Lipoma of the Stomach H Verger and C Massias —p 236
Technic of Duodenal Intubation L Damade —p 237

Irradiation of the Spleen in Treatment of Tuberculosis—Mauriac urges caution in irradiation of the spleen in treatment of tuberculosis, and says that many objections can be made to Manoukhin's assumption that leukocytolysis is a defensive reaction, and the fragility of leukocytes the therapeutic aim to be reached Complex phenomena occur in irradiation of the spleen, and research should be made on the modifications of the spleen and the blood during treatment Manoukhin considers only the effect produced on the leukocytes Mauriac says that, before treatment, the blood count and the fragility index of the corpuscles should be determined After each application the blood should be examined by the differential count, merely counting the total leukocytes is not very instructive A patient with abnormally fragile white corpuscles should not be subjected to induced leukolysis Scientific study should be made of the blood reactions, the effect on the red corpuscles and the leukocytes of various methods of irradiation of the spleen, bone marrow, and glands and their indications, as this new treatment of tuberculosis deserves to be considered from a scientific standpoint (The Manoukhin method was described further in these columns May 27, 1922, p 1671)

Lipoma of the Stomach—Verger and Massias report a case of submucous lipoma of the stomach, which they state is exceedingly rare, as they know of only seven cases of submucous lipoma of the stomach that have been previously published

Treatment of Asthma P Minvielle—p 627

Pregnancy Complicating Pulmonary Tuberculosis—Bar places great reliance on a lively reaction to tuberculin early in the pregnancy as a sign that the woman has resisting powers enough to stand the strain of childbirth If the reaction is weak, he interrupts the pregnancy before the close of the fourth month, preferably by hysterectomy, unless the woman is young and there is hope of recovery In his extensive experience he has induced abortion only in nine cases in the last fifteen years One patient died three years later, but the others regained their health and three have had normal pregnancies since Hysterectomy in fifteen cases was always followed by marked improvement, and only one in this group died a few months later The dire effects of involution of the uterus can be obviated by hysterectomy at term This gave good results in the one case managed in this way

Sputum Examination—How to avoid being misled by secondary infection is the subject discussed by Bezançon The sputum should be fresh, not more than two or four hours old He stirs the sputum around in physiologic saline in a Petri dish until no more bubbles form, rinsing through two to four dishes is generally enough Two smears are made with the sputum and one is stained with the Gram the other with the Ziehl-Nielsen In 23 of 29 cases thus examined nothing but tubercle bacilli were found, and they were thus responsible for the hectic fever Pneumococci were numerous in most of the 6 other cases, and they probably were responsible for the flaring up of the latent tuberculosis

Vaccine Prophylaxis and Therapy of Tuberculosis—Arloing relates that the S Arloing method of preventive vaccination of cattle has proved a practical, harmless and certain method of protecting cattle against tuberculosis in from 75 to 80 per cent The protection conferred lasts from fifteen to eighteen months, at this time the vaccination should be repeated Maraghano's preventive vaccination of human beings has now been applied for twenty years and has proved harmless and effectual He has a record now of 3 702 persons thus vaccinated children and adults, in tuberculous families Of 1,893 traced for ten years only eleven have developed tuberculosis Agglutination the opsonins precipitins etc acquire all the characteristics of immunity The Rappin method has been applied to man and cattle since 1917 Dried and crushed human tubercle bacilli are emulsified for seven days in a 3 per cent solution of sodium fluorid then rinsed and added to a very active antituberculosis serum In three days this serovaccine is ready In 400 guinea-pigs with grave tuberculous infection, this serovaccine aborted the disease, the manifestations being restricted to the local gland, and the process did not reach the cheesy stage Children and adults vaccinated with it by scarifications seem to be protected against the disease and local and general improvement has followed its use with established infection Professor Rappin has been studying vaccine therapy of tuberculosis for twenty years at the Pasteur Institute at Nantes

Tuberculosis in the Dog and the Cat—From 10 to 15 per cent of the cats and dogs examined postmortem by Petit showed tuberculous lesions analogous to those in man These animals acquire tuberculosis readily from man and are liable to prove sources of contagion

The Complement Fixation Test for Tuberculosis—Guinard and Botkine have compiled 2 513 instances of serodiagnosis in absolutely certain cases of pulmonary tuberculosis, with positive fixation of complement in only 84 27 per cent The proportion is still less with other forms of tuberculosis 66 per cent in tuberculous peritonitis, 33 46 and 50 per cent in serofibrinous pleurisy 70 per cent with active bone and joint lesions, and 23 per cent with inactive In 530 personally observed cases, the reaction was negative in from 7 89 per cent to 16 66 per cent in the groups of active tuberculosis and in 67 56 per cent of the healed cases while it was positive in 67 35 of 98 others who seemed to be free from tuberculosis Parallel tests were made with Besredka's egg culture antigen, Calmette's peptone antigen, and Negre and Boquet's methyl alcohol antigen

Pleomorphism of Tubercle Bacilli—Vaudremer presents evidence that the resistance to acids of the tubercle bacillus is an acquired property, as tubercle bacilli cultures grown deep in potato bouillon are not acid resistant and they pass through the Chamberland filter They are pathogenic and are agglutinated by tuberculous serum Resown on glycerined potato they return to the classic, acid resistant type They present evidence further that the production of tuberculin is not a constant phenomenon, but occurs only when the medium contains albuminoid substances Both acid resistance and tuberculin production can be done away with by macerating the tubercle bacilli in an extract of *Aspergillus fumigatus* or of *Penicillium glaucum* They can then be taken up by the phagocytes without killing the latter

*Obstruction of Cystic Duct C Daniel and A Babes—p 377
Treatment of Pott's Disease E Sorrel—p 378

The Gallbladder with Obstructed Outlet—Daniel and Babes found profuse mucous secretion in the gallbladder with a calculus plugging the cystic duct There was no trace of bile The catarrhal inflammation of the gallbladder probably yields to sclerosis at a later stage

Pott's Disease—Sorrel is surgeon in chief at the Berck seashore hospital, and his extensive experience teaches that children with vertebral caries should always be kept horizontal They can lie on the back with a pad to raise the lumbar region or they can lie prone when the lesion is in the lumbar region In the dorsal region a corset must be worn besides He has the corset strapped to the light spring on which the child lies, and with which it is moved about With the lesion in the neck a minerva has to be applied This treatment should be kept up until the anatomic cure is complete This anatomic cure, the soldering together of the diseased vertebrae requires at least three years from the beginning of the disease and as it is impossible to determine this with precision extreme caution is necessary when the child is allowed to get up A plaster corset should be worn for a time and a celluloid or leather corset for years afterward A spontaneous cure is almost invariable in children but is very rare in adults Reclining during the active stage is as important for adults as for children but after the acute phase is past operative means to insure ankylosis is a valuable aid Before this, it is dangerous

Diathermy for Chronic Urethritis Martin Mackintosh—p 552
Importance of Proper Classifying of Abnormal Delinquent and Abandoned Children L. Crampi—p 558

Ileus from Tuberculous Peritonitis—Gallo gives details of 12 cases, all adults except 2 girls of 15, both of whom died, as also one young man In the others the obstruction in the intestines yielded to medical or surgical measures One had several attacks of obstruction The obstruction was mechanical in 4 from retraction of the fibrous mesentery In 4 cases paralysis of the bowel was responsible for the ileus In this paralytic form, operative measures are useless and do harm There is less pain than with mechanical ileus, and no peristalsis, and auscultation is negative After recovery from the ileus, in several the peritonitis improved under heliotherapy, etc In one little girl several loops of intestines were found welded together, and the aspect suggested tuberculous peritonitis until the discovery of a ruptured ovarian abscess Complete recovery followed

Electrode for Diathermy in Chronic Urethritis—As the electric current always follows the shortest path between the two electrodes, it is difficult to insure an even action throughout the entire length of the urethra Mackintosh gives illustrations of the device which he has been using for two years with constant satisfaction A large plate slips under the sacrum, another lies on the pubis, both strapped to the table, and a standard in the crotch connects both the whole forming the negative electrode There is no narrow path between the electrodes but a broad field for the current to spread on all sides from the positive electrode in the urethra The heat can be graduated from 43 to 45 C was found most effectual, the sittings from one half to an hour long, to a total of from ten to twenty

Occult Spina Bifida A Hintze—p 409
*Plastic Operation on Pericardium H Klose—p 455
*Surgery of the Pericardium H Klose and H Strauss—p 467
*Pseudarthrosis E Lexer—p 520
*Regeneration of Tendons A Salomon—p 608

Occult Spina Bifida—Hintze summarizes the literature on this subject from Virchow, in 1875, to date and discusses the difference between the normal sacral fontanel and the pathologic spina bifida No traces of the lumbar sacral fontanel or skull fontanels were found in 150 skeletons of anthropoid apes examined, and nothing like human fontanels was found in a new-born chimpanzee He discusses further the findings in 400 human sacrums, and the roentgenograms of 700 others, and in cases of lumbosacral hypertrichosis and neuroparalytic disturbance of one or both legs, with or without bladder disturbances—all traceable to some anomaly in the lower spine

Plastic Operations on the Pericardium—Klose's experimental research in this line was described Jan 21, 1922, p 253 This article analyzes the healing process

Operative Treatment of Suppurative Pericarditis—Klose and Strauss tabulate from the literature 29 cases of suppurative pericarditis treated by puncture alone, all fatal but 4 27 treated by an intercostal incision, with recovery of 10, 37 treated by exposing the pericardium extensively, curing all but 16 of the 37 They describe the differential diagnosis, saying that it is difficult, and emphasizing the importance of clearing out the exudate from the pericardium at the earliest possible moment For this, the bony wall has to be resected and the pericardium has to be effectually rinsed out with physiologic saline and amply drained, as they describe If adhesions develop, a plastic operation with omentum or fat is justified, and they report a case of the kind in a man of 41 The mediastinopericarditis and pleural empyema had entailed extreme insufficiency of the heart, but the patient bore well the transplantation of a flap of fat to fill the gap left by the retraction of the pericardium after it had been incised The heart functioning progressively improved, evident especially in the diuresis The fourth day the man died suddenly As purulent pericarditis is often preceded by a nonsuppurating phase, this justifies early operative intervention when pyogenic bacteria are involved, even when the effusion is not purulent The diagnosis can be confirmed by exploratory puncture in the left rib-xiphoid angle Recovery has been observed in 10 4 per cent of the cases treated by multiple puncture, in 37 per cent after intercostal incision, and in 56 7 per cent after extensively opening up and draining the pericardium Treatment must aim to prevent adhesion The operation can be done under local anesthesia, treating the pericardium itself with a 10 per cent. solution of cocain The opening of the pericardium and change of dressing should be done under overpressure Pneumocardium can be warded off later with rubber tissue by E Rehn's method Intake of fluids should be restricted Chloral should be avoided The combination of surgical and conservative measures, heart stimulants, etc, will save many a patient who fifty years ago would certainly have died A bibliography of 230 titles is appended

Origin of Pseudarthrosis—Lexer ascribes great importance to the injury of the vessels at the time of the fracture or transplantation of bone

Restitution of Tendons—Salomon resected part of the Achilles tendon in dogs and a few cats and studied the regeneration process under various conditions The fact that regeneration occurred even when the corresponding muscle had been resected teaches that functional stimulation is not necessary for regeneration of a tendon In the dogs the gap in the muscle grew up with tendon tissue Regeneration of a tendon cannot proceed from muscle alone During the first phase of regeneration, functional stimulation is futile or directly injurious, but during the second stage of the regeneration it is a factor of constantly increasing importance for perfect regeneration in man and animals

Psychanalysis in Treatment of Tic—Trepsat reports the complete cure in a few days with Freud's method, of a man of 27 with an intense tic of remarkable frequency—a spasm of almost the entire body He says that the sentimental complex which is the origin of the tic should be looked for 'A tic, at the onset is always an indication of suppressed impulses" We must look for vasomotor and secretory disturbances also, inducing motor disturbances The will and especially the motor functions should be reeducated, and psychanalysis is the best method to use for the purpose Trepsat regrets the diffusion given today to this principle and method, as he believes that psychanalysis should be applied without the patient's knowledge, and remarks in conclusion 'We should always bear this therapeutic procedure in mind, use it sometimes, and never speak of it"

*Splenic Anemia in Children S de Stefano —p 385
*Hemoclastic Crisis in Children M Misasi and G Aiello —p 408

Splenic Anemia in Children—De Stefano gives the details of 13 cases in which there was inherited syphilis, and 6 in which there was a history of both syphilis and tuberculosis in the family These inherited taints entail dystrophia of the blood-producing system, and this is responsible for the splenic anemia, and explains the inefficacy of specific treatment It also explains the development of the splenic anemia in older children as some superposed occasional factor aggravates the abnormal condition In 2 of these cases tuberculosis alone could be incriminated, and in 2 others no special cause could be detected There was irregular fever in 19 of the total 23 cases, but it was never so severe or characteristic as in the splenic anemia of leishmaniasis, kala azar in which there may be two attacks during the day

The Hemoclastic Crisis in Children—Misasi and Aiello confirm that leukopenia after ingestion of milk is a physiologic phenomenon in children under 10 The drop in the leukocyte count is more pronounced, the younger the child With digestive derangement in infants and with congenital syphilis, leukocytosis may be observed instead With signs of liver disease, the leukopenia was often intense The research was done on 6 normal children, 9 with dyspepsia, 4 with insufficiency of the liver, and 2 other sick children

*Precipitation Velocity of Blood Corpuscles W Lohr —p 388
Insomnia A Hoche —p 389
Course in Dermatologic Technic H M Joseph —p 391

Reliable Serodiagnosis of Tuberculosis—Kempner confirms that in the extract of tubercle bacilli grown on an egg culture medium—Besredka's antigen—we have a means for certain and specific fixation of complement in the diagnosis of tuberculosis She gives the details of 275 of the 350 persons tested, including positive findings in 82 per cent of the 131 supposed tuberculous and only 3 5 per cent in fifty-seven supposedly healthy persons Repetitions of the test elicited the same response each time A positive reaction is almost invariably a sign of an active tuberculous focus but a negative reaction does not exclude a healed or latent focus She found further that the Sachs test elicited a positive reaction at the second hour in the tuberculous, but it had veered to negative by the eighteenth In the syphilitic, on the other hand the reaction was negative at the second hour but became positive by the eighteenth

Precipitation Velocity of Blood Corpuscles in the Diagnosis of Surgical Affections—Lohr found in a group of 100 uncomplicated fractures an increased rate of precipitation of blood corpuscles in all cases In the most severe fractures the increase was noted twelve hours after the accident at the earliest, but always after twenty-four hours In hundreds of other surgical cases it was observed that the rate of precipitation paralleled the size of the area affected by the inflammation or the amount of degeneration in a tumor This finding has practical diagnostic value in abdominal surgery, in order to form a judgment in regard to the size of the affected area especially in appendicitis for during the intervals in which the inflammation dies down there is no increase in the precipitation rate

Blood Sugar in Addison's Disease, Action of Epinephrin—Rosenow and Jaguttis refer to Porges' view that a reduction of blood sugar values, which he found in three patients with Addison's disease and also in animal experimentation after removal of the suprarenals, is a characteristic finding associated with the suspension of suprarenal functioning On the basis of a critical survey of the cases previously reported and researches on a patient, the writers conclude that hypoglycemia is not a constant symptom of Addison's disease The discrepancy in the reports of various authors is doubtless due to the fact that only one blood sugar test was made They find that in Addison patients as in normal persons, the blood sugar values fluctuate greatly from day to day Therefore before a given case of Addison's disease can be said to present low blood sugar values several tests (fasting) should be made on different days The intramuscular injection of epinephrin causes in an Addison patient a hyperglycemia, the maximum one hour after the injection The larger the quantity of epinephrin employed, the more marked is the hyperglycemia But whereas in a normal person, when large doses of epinephrin are used the blood sugar curve after reaching the maximal value quickly drops below the initial record, this secondary hypoglycemia is not recorded in the Addison patient After the injection of 2 mg of epinephrin the normal control excreted sugar in the urine, whereas the Addison patient presented no glycosuria

The Practical Importance of the Alimentary Hyperglycemia Curve—Rosenberg points out that examination of the blood and the urinary sugar following ingestion of 100 gm of glucose makes it possible to clear up many, though not all, obscure cases of glycosuria He has seen some cases in which even this test failed to discover the cause of the glycosuria which usually appeared only intermittently He recommends the method for the recognition of a latent diabetes, and in endosecretory affections for the discovery of disturbances of carbohydrate metabolism, which otherwise elude the investigator Following the ingestion of 100 gm of glucose in a normal person, the blood sugar reaches the apex in from one half to one hour, and after two hours the blood sugar has become normal or virtually normal In a diabetic the reaction is essentially different The blood sugar curve rises higher, the apex is not reached under an hour and a half and usually only after more than two hours In the urine of otherwise aglycosuric patients glycosuria appears There is a certain parallelism between the gravity of the diabetic disturbances of metabolism and the slope and duration of the blood sugar curve We are thus able to discover a threatening diabetes before glycosuria is regularly present, and by instituting appropriate therapeutic measures influence the course of the disease with greater chances of success

The Diagnostic Value of the Atropin Test Applied to the Pylorus—Otvos has found the atropin sulphate test of diagnostic value in internal medicine It is independent of the chemical reaction of the gastric juice A positive reaction usually points to organic disease, mainly to a hard duodenal or gastric ulcer The test will often establish the cause of peripyloric adhesions The test is more often positive with callous duodenal ulcer than in affections of the bile ducts, which usually present a characteristic syndrome In simple cholecystitis without adhesions the atropin reaction is usually negative In the presence of ptosis and atonia a positive atropin reaction has no diagnostic value While it is true that the atropin test does not furnish a direct diagnosis it has its place in the objective consideration of every case, and may be regarded as pointing to an 'indirect ulcer symptom"

The Course of Syphilis Without Treatment—Spiethoff states as the result of his observations on the strength of the Wassermann reaction in untreated cases of syphilis, that such experience is valuable in throwing light on the course of cases under treatment Also on many peculiar manifestations that arise during treatment for example the positive fluctuations in the strength of the Wassermann reaction and the sudden appearance of manifest clinical symptoms Such manifestations may be interpreted as provocation symptoms of treatment, as the expression of inadequate therapeutics as the result of a quantitative or qualitative error in the selection of a remedy or as evidence of a recurrent strain in a certain stage of development that rendered it immune to attack In observing untreated cases, the Wassermann test

should be applied frequently, at the same time that all other manifestations are carefully studied, for thus the therapeutist becomes familiar with the fundamental type of case

Histologic Researches on the Endosecretory Glands in Psychic Affections—In 25 patients with mental disease Fauser and Heddaeus examined the thyroid the suprarenals, the hypophysis the genital glands, and in some instances also the thymus and the epiphysis Seven patients belonged to the dementia praecox class, 12 were epileptics, 5 were imbeciles, and there was one case of senile dementia In the thyroids of such patients goitrous degeneration was frequent, other changes were occasioned by concomitant affections (tuberculosis) The suprarenals showed in part senile changes and in part finding due to tuberculosis In the hypophysis, there was found in various psychoses, a predominance of the basophiles over the eosinophiles in the anterior lobe, which is exactly opposed to the findings in healthy persons of corresponding age and may possibly be regarded as a sort of retardation of function of the hypophysis The genital glands, the thymus and the epiphysis showed no typical changes If we may be allowed to generalize on these findings, it may be stated that only in exophthalmic goiter could infantilism of the endocrine glands be demonstrated histologically—not in psychoses such as they investigated More extensive investigations may bring to light characteristic changes

Infant Mortality and Causes of Death in Infants During the War—Rott endorses the view that the significant decrease in the percentage of deaths in infants from gastro-intestinal catarrh and from cholera nostras is due to the fact that, during the war, more infants were breast fed

Present Status of Epilepsy K Singer—p 540
Present Status of Tartar Emetic M Mayer—p 541

Treatment of Muscular Spasms—Pal explains how treatment must differ according as the spasm is the result of hypertonia or hyperkinesia or is a permanent contracture Psychic and reflex causes must be combated and the stimulus to the hyperkinesia modified He warns against a drug to deaden the pain as merely a convenient makeshift We can act on the spasm by checking the action of the nerve innervating the muscle, the vagus and pelvic nerves are inhibited peripherally by atropin The muscle itself can be influenced by papaverin emetin camphor or benzyl compounds The third factor, the sympathetic nerve, might also be acted on, epinephrin may be useful for this but is not reliable by the mouth, especially with spasm in the lower bowel Local heat reduces the movements and excitability of the bowel With permanent contracture, internal medication is futile but spasm in esophagus and rectum may be accessible to local medication

Anginosis—Imhofer agrees with those who regard angina—infectious sore throat—as more than mere tonsillitis It is a general infection, and the tonsils are only one link in the chain The kidney and joint disturbances that have been observed after anginas form part of the original syndrome It only comes to an earlier manifestation in the tonsils, and tonsillectomy removes a particularly favorable field for its manifestations to develop Hence the term anginosis" is descriptive He urges all who encounter cases of actual angina after tonsillectomy to study them with special care He also emphasizes that this conception of anginosis calls for general treatment, not merely spraying the tonsils General treatment by parenteral injection of milk seems promising and the one case in which he tried it seemed to stamp this anginosis as a particularly favorable field for protein therapy

Treatment of Paralysis Agitans—Franke reports improvement in a case of grave paralysis agitans under calcium chlorid which seems to have something of a causal action in this disease It had the drawback of increasing immeasurably the output of urine This may have been a bladder neurosis in the woman of 65, as it yielded to phenobarbital Thus improved conditions materially, and was kept up for the three years of her life relieving her of cramps and tremor although the disease progressed otherwise She took 0 05 gm of phenobarbital three times a day He cites also a case of rotary tic of the head which yielded in five months to a solution of 100 parts calcium chlorid in 500 parts distilled water An eight months' course cured likewise a case of convulsive tic of the neck muscles

Spirochetal Jaundice as Result of Industrial Accident—The man of 62 developed fatal spirochetal jaundice two weeks after a fall into a cesspool An analogous case was published by Stirl The right to workmen's compensation was recognized in both cases

Septic Abortion—Grube relates that he always evacuates the uterus with septic abortion and in twenty years has never had a death from this cause This is also the practice of the practitioners he has consulted He thinks it is much the lesser evil outside of institutions

Specific Gravity of Small Amounts of Urine—When the amount is too small for the ureometer Kirch adds more urine with known specific gravity He gives the formula with which the calculation can be easily done

The Time Question in Deep Roentgentherapy A Haupt—p 75

Importance of Placenta for Duration of Pregnancy—De Snoo argues that the placenta has an inhibiting influence on the uterus musculature As the placenta grows old, this influence grows less The logical inference that a tendency to habitual abortion can be combated by administering placenta extract has proved its correctness in many instances in his experience, abortion or miscarriage thus being warded off He ascribes this action to the trophoblast which, he says, has its separate existence and life course It loses its vitality after the ninth month, and this starts the birth process This trophoblast in powder form seems to pass through the digestive tract without loss of its special features A normal placenta yields about 20 gm of powder, and he gives from 3 to 6 gm by the mouth daily By this means patients have been tided along to term who under all other measures had regularly aborted or miscarried He regards the placenta powder as indicated further in all cases when the contracting forces of the uterus are working too vigorously

Torsion of the Uterus—In Vogt's case the uterus in labor had twisted at least 180 degrees After cesarean section it righted itself

Diagnostic Importance of Behavior of Cerebrospinal Fluid in Experimental Syphilis in Rabbits—Plaut and Mulzer report that pleocytosis is frequently the first symptom of syphilis in rabbits following experimental inoculation with the disease Through examination of the spinal fluid one can assure oneself that the inoculation has been successful before any other evidence is forthcoming, and more particularly, before the site of the inoculation shows any reaction whatever Often, orchitis or the primary effect appeared only weeks or months after a number of positive tests of the cerebrospinal fluid had been made In one rabbit, syphilis of the testicle developed six months after the inoculation, whereas pleocytosis was noted in the spinal fluid as early as five weeks after inoculation In fact, in some animals, pleocytosis remained the only symptom and during a long period of observation, no external signs of the infection were recognizable It is thus evident that changes in the spinal fluid may be not only the first but for a considerable period of time (possibly throughout the whole course of disease) the only sign of syphilis in the rabbit

Ether Therapy and Prophylaxis of Peritonitis—Sigwart reported four years ago his experiences with the injection of ether into the abdominal cavity in diffuse peritonitis The results at that time had been very favorable, of 11 cases of diffuse peritonitis only one resulted fatally, and here death occurred eighteen days after the operation, from gangrene of lung In his first trials of ether therapy he counted on some severe manifestations of shock but was surprised to note nothing more serious than retarded respiration and cessation of respiratory movements for short periods However, in the present series of cases in which prophylactic injections of ether were employed he witnessed several severe manifestations of shock and in one instance he feared for a time a fatal outcome, and it took several hours before the woman was out of danger He thinks these accidents were due to lack of drainage or ventilation, and that they can be avoided in the future by not closing the abdomen so soon after the injection of the ether He still ascribes to ether great therapeutic value as a means of warding off peritonitis in an infected pelvic cavity He uses as high as 250 c c of ether

White Necrosis of the Placenta E Clemenz —p 758
Bacteriology of Umbilical Cord H Kustner —p 771

Placenta Accreta—When the placenta has grown into the wall of the uterus, it is impossible to separate it, and the only recourse is prompt hysterectomy Dietrich had a case of the kind and has found records of nineteen similar cases in which the basal decidua was lacking, and the villi grew directly into the muscular wall Death from hemorrhage is the rule in these cases

Heat in Treatment of Gonorrhea in Women—Frank has used in fifty cases a flexible metal sound which is heated by electricity to a temperature up to 55°C This applies heat to the mucous membrane of the urethra and cervix, and thus induces a healing hyperemia while reducing the vitality of micro organisms He regards the results as very encouraging in old refractory cases

Pregnancy Toxic Degeneration of Liver—A case of acute yellow atrophy of the liver in an otherwise healthy young woman in the second or third month of pregnancy is described, with the necropsy findings

Pregnancy Angiospasms—Tests of forty-six nonpregnant women and 150 tracings from a large number of the pregnant have apparently confirmed the great importance of recording the spasmodic contractions of the blood vessels the capillaries in particular It allows insight into pathologic conditions from an entirely different standpoint The circulation of the blood in the pregnant is altered even at points remote from any mechanical influence The angiospasms are affected remarkably by the labor contractions, this tends to refute the assumption that toxic factors are responsible for the angiospasms The vascular tonus in the pregnant will repay further study

Fruits and Seeds—Ahlfeld here reviews his long life work as a gynecologist and obstetrician, and lingers on certain features which he regards as achievements and others which he hopes will prove fruitful seed One of his 'fruits' is the examination of the woman near term, the abdomen exposed the patient placed high enough so the observer does not have to stoop Simple prolonged quiet inspection of the abdominal wall when the wall is thin will reveal conditions in the uterus showing congested vessels to be avoided in section and other data Direct auscultation of the uterus he has always found more instructive than with a stethoscope Fetal singultus seems to be a physiologic process, as also the rhythmic movements of the fetal respiratory muscles to which he first called attention He is convinced that alcohol destroys the bacteria dangerous for puerperal infection, the alcohol makes its way into the skin One of Ahlfeld's precautions is to use a glass tube in the vagina for the preliminary cleansing The fluid thus hits the cervix first and flows out, instead of washing the bacteria already in the vagina back to the cervix

Differential Diagnosis of the Uterus—Marx discusses how to distinguish in dubious cases between abortion, pregnancy and disease In a case encountered the sepsis after abortion had been complicated with a gas-forming infectious process in the uterus and the blood in the urine and pouch of Douglas showed only methemoglobin evidently from bacterial action

*Sodium Lactate in Treatment of Acetonemia E Modigliani —p 129
Congenital Ptosis of Eyelids Two Cases G Squarti —p 146
*Invagination of Colon P Iacchi —p 159

Sodium Lactate in Treatment of Acetonemia—Modigliani advocates this treatment as effectual and harmless, it is a normal constituent of the blood that probably is lacking in acid intoxication It does not cause symptoms of intolerance even given to infants up to 30 gm per day It is easily oxidized being rapidly transformed into sodium carbonate in the blood, and this is eliminated in the urine It has a strongly alkaline action on the blood and urine, neutralizing the excess of acid, and promoting oxidations which aid in the transformation of the acetone bodies and thus ward off production of acetone He has used it in thirteen cases, giving from 12 to 30 gm at first and then less in the following three or four days The urine became alkaline by the second day in all, and the tests for acetone were negative by the third or fourth day, and the headache, vomiting fever, dyspnea and the odor on the breath promptly subsided The sodium lactate can be generated at the time by mixing in 30 c.c of hot water 2 tablespoonfuls of 10 per cent solution of lactic acid in distilled water and 2 tablespoonfuls of 7 5 per cent solution of sodium bicarbonate In four of five cases there has been no return of the acetonemia in the fourteen to sixteen months since

Invagination of the Colon—Iacchi manipulated the invaginatum through the rectum of the infant of 9 months The invaginated portion protruded into the rectum, and he succeeded in reducing it by taxis in this way

The Bladder in Colon Bacillus Sepsis S Werboff —p 151
*Calculi in Bladder A Nakajima —p 155
*Actinomycosis of Kidney H Pinner —p 187

Function of Kidney Calix—Haebler confirms Wassink's statements in regard to the peristalsis of the normal kidney pelvis and calices of living mammals There is not only a circular contraction, but lengthwise, 'milking' movements

Calculi in Bladder—Nakajima's long study of bladder stones their varieties, almost universal geographical distribution, and origin incriminates uric acid and calcium as indispensable for the formation of calculi in the bladder The calculus requires further some organic albuminoid substance, and for this some pathologic change in the kidneys is responsible

Actinomycosis of the Kidney—The kidney lesion accompanied actinomycosis of the lungs and pleura in the case described with an illustration There had been an interval of two years before the kidney symptoms had developed Only 7 instances are known of primary actinomycosis of the kidney, but in 460 cases of actinomycosis of chest or abdomen, secondary infection of the kidney occurred in 16 Pinner's patient was a previously healthy man who used to chew grain stalks as he unloaded barley in working for a brewery He had apparently recovered after an operation on the chest and recovery was smooth after the nephrectomy

The Schauman Festskrift—The seventeen articles in this number of 217 pages form a memorial tribute, as Schauman died a few weeks before his sixtieth birthday for which the *Festskrift* was planned All the articles are in German except one in English on page 371

The Psychotechnic of Piano Playing—For this study Tigerstedt had an electric recording drum connected with the keys of the piano

The Arteries of the Kidney and High Blood Pressure—Wallgren declares that the evidence to date is inconclusive as to whether the changes in the renal arterioles precede or follow the high blood pressure

The Mendelian Laws in Human Heredity—Federley discusses how best to study the mendelian laws as they affect human beings, remarking on the many difficulties encountered in study of human heredity The main thing now, he reiterates, is to compile data, collecting material and tracing family strains through generations When sufficient data have been accumulated research on heredity can proceed on a reliable basis, whereas now it is mostly mere surmise

Heredity and Pernicious Anemia—Mustelin refers to Schauman's series of twenty-four families with two or more cases of pernicious anemia, and he adds a new family to the list It is the first on record in which pernicious anemia was known in three generations mother daughter and granddaughter Meulengracht has published an instance of five cases in one Danish family The disease grew more severe and developed earlier in each succeeding generation

Remissions in Pernicious Anemia—Willebrand's patient presented the signs and symptoms of pernicious anemia ten years ago, but they have subsided during the last few years The findings now are merely those of ordinary anemia gastric secretion has been approximately normal throughout

Stenosis in Small Intestine and Pernicious Anemia—Meulengracht reports another case of pernicious anemia developing in a woman of 64 with three strictures in a certain segment of the small intestine

Capillary Circulation in Pernicious Anemia—The research on fourteen cases showed characteristic findings in the capillaries in this disease

Chronic Stomach Disease—Ehrstrom comments on the paucity of our knowledge of this subject

The Sex in Relation to Appendicitis—Backman relates that the male cases only slightly predominated in his 274 cases of destructive appendicitis, while women formed 70 6 per cent of the 659 cases of the catarrhal type of the disease

Renal Diabetes—Johnsson found sugar in the urine on repeated examination during ten and sixteen years in his two cases The sugar content of the blood was found normal always, fasting The father of one of the patients is a diabetic, and two brothers show symptoms of slight diabetes The sugar test was followed by a subnormal and a normal response in his two cases

Water Deficit and Acetone Excretion.—Ehrstrom queries whether relative water deficit plus carbohydrate starvation provides the conditions for abnormal acetone excretion His experience testifies to this assumption

Acta Paediatrica, Stockholm

April 15 1922 1, No 4

*Rachitis J Jundell —p 355
*Acid in Infants Blood and Urine T Stenstrom —p 381
*Hydrochloric Acid in Infants I Chievitz —p 416
Aregenerative Aplastic Anemia in Boy of 4 N Malmberg —p 438
Index of Nutrition E Nobel —p 449 Idem U Hjarne —p 452

Pathogenesis and Treatment of Rachitis—Jundell treats rachitis systematically and consistently with relative inanition, and his excellent results with this method have been already recorded in these columns This alone cures in the mild cases, and when supplemented with cod liver oil and phosphorus, even the severest cases have always yielded to it in a month or two The calories are reduced to 65 or 70 per kilogram, the milk to 60 or 75 c c per kilogram The rest of the calories are obtained from sugar and flour, and, as soon as practicable potatoes and grits vegetables and fruit are given Tea, beef tea, cocoa or fruit syrup are also given, the total intake of fluid not surpassing 1 liter a day during the first year of life The rapid recovery from rickets during this relative inanition, and the fact that rachitis does not develop in children with pylorospasm or other condition entailing protracted inanition sustain his view that overstrain of the general nutritive functions of certain endocrine glands seems the most plausible explanation of rickets By reducing the intake of food we ward off and reduce this overstrain (In English)

Acid Content of Blood and Urine of Infants with Nutritional Disturbance—Stenstrom gives the tabulated data from eleven male infants, three of them healthy The metabolic findings showed actual acidosis after the fat element in the food had been increased for the eight infants with dystrophia and this was possible also in the one healthy infant tested The production of acid was not increased by augmenting the carbohydrate content of breast milk, but with cow's milk the acid increased in one dystrophic infant As the acid increased the excretion of nitrogen decreased

Hydrochloric Acid Secretion in Infants—Chievitz classifies fifty-three infants in various groups and tabulates the details of the findings after the barley gruel test meal No instance of congenital achylia was discovered but there was achylia or hypochylia *in about half the cases of essential digestive* disease In the healthy, the values of the free hydrochloric acid averaged Gunzberg 8, Congo 11, and phenolphthalein 14

Hospitalstidende, Copenhagen

March 18 1922 65, No 8

*Vaccine Treatment of Urinary Infections O Wulff —p 17 Concn No 10 p 157

Vaccine Treatment of Urinary Infections—This communication summarizes what has been published in this line and the experiences with 108 patients in Rovsing's service in the last ten years, including 8 under 15 years of age There were only 20 men to 88 women The colon bacillus was responsible in 92 and the staphylococcus alone in 8 A spontaneous cure of infection of the urinary passages is of extremely rare occurrence The acute symptoms subside but the infection persists, it always bears the chronic imprint Vaccine therapy aided in eradicating it in many of the cases recorded Those reporting favorable results with it were always those with the longest series of cases All are agreed on the necessity for autogenous vaccines and for beginning with small doses Wulff gave up to 10,000 millions and over The tolerance and the clinical action are the guide, estimation of the opsonins is too tedious The tolerance varies widely, and slight by-effects are liable to be observed The duration of the immunization is a question, the intervals since without recurrence have been up to twelve years In the experience of large numbers of clinicians 20 per cent of the patients seem to be refractory Vaccine treatment as a preliminary to operations on infected urinary passages seems promising, but has not been tried on a large scale yet

ENDOCRINOLOGY *

LEWELLYS F. BARKER, M.D.
BALTIMORE

This symposium on internal secretions includes several papers that deal chiefly with the physiologic, the pathologic and the therapeutic effects of endocrine substances. I have been asked to make, by way of introduction, some general remarks on the subject of endocrinology as a whole. A discussion of the topic is timely and should be of value to workers in every branch of medicine. The profession in general is evincing a lively interest in the internal secretions, as is shown by the titles of papers read at medical meetings. An association for the study of the internal secretions already has a large membership, and its special journal, *Endocrinology*, is widely read.

THE ENDOCRINE ORGANS

Organs of the body that yield to the blood, in addition to the common metabolites resulting from the general life processes of cells, certain specific products that influence distant parts have been designated "endocrine organs," and the special substances thus yielded are known as "internal secretions." These endocrine organs have sometimes been called the "glands of internal secretion" because their products are distributed to the circulating fluids of the body itself rather than to the world outside or to tubular canals that communicate with the external world. They have sometimes been called "ductless glands," to distinguish them from glands whose products emerge through epithelial lined channels, though it should be remembered that in some organs, like the pancreas, we have some parts producing an external secretion discharged through a duct and other parts producing an internal secretion that is discharged directly into the lymph or blood without the intermediation of a duct. Recently, the endocrine organs have been spoken of as "incretory organs," the specific substances they produce being known as "incretions," to distinguish them from the "secretions" and the "excretions" of other glands.

The principal endocrine organs are the thyroid, the parathyroids, the thymus gland, the lymph glands, the suprarenal glands, the gonads, the hypophysis cerebri (or pituitary gland), the epiphysis cerebri (or pineal gland), and the insular tissue of the pancreas (islands of Langerhans), though it is quite possible that other organs, as the spleen, the kidneys, the liver, the salivary glands and the prostate, also perform endocrine functions in addition to their other physiologic activities.

In agreement with the idea that the specific substances produced by the endocrine organs are carried by the blood or lymph to distant parts, modifying the activity of the cells there, the term hormone was suggested for these substances by Bayliss and Starling. It is quite possible, however, that some of these incretions, instead of acting as excitants or depressants of distant cells, as the hormones are supposed to do, perform the function of neutralizing poisonous substances circulating in the blood. Such hypothetic detoxicants have been designated "negative incretions," to distinguish them from true hormones, or "positive recrementitious incretions."

FUNCTIONS OF THE ENDOCRINE ORGANS

The ways in which the specific products of the endocrine organs influence the rest of the body are gradually being found out. Progress has been especially rapid since the more exact chemical nature of some of the specific substances produced has been discovered, making it possible to apply more extensively experimental methods to the study of hormonal activities. Epinephrin, isolated from the chromaffin tissues, thyroxin from the thyroid, pituitary extract from the hypophysis cerebri, and, very recently, insulin from the islands of Langerhans of the pancreas, are notable instances of incretory substances, or extracts, useful for experimental work. Physiologic investigators, as well as pharmacologists, have been busily engaged in determining by animal experiment the influences of these substances, or extracts, when introduced by various routes, on the physiologic processes in the different organs and tissues. Clinicians are comparing, in diseased human beings, the effects of these purer substances or extracts with the effects producible by administration of the fresh, or dried, organ substance as a whole. It is scarcely conceivable that an endocrine organ produces only a single important substance, as thyroxin in the case of the thyroid or epinephrin in the case of the chromaffin tissue, it would seem probable that each gland may produce at least several substances, even though our attention may at present be focused on only one.

Many of our ideas concerning the functions of the individual endocrine organs have been derived from extirpation experiments in which the effects on the animal operated on have been noted and the curative influences of substitutive therapy (organ transplantation, dried gland administration) have been observed. Even more important, perhaps, have been the clinical-pathologic studies that have correlated either anomalies of constitution or disease syndromes with demonstrable pathologic-histologic alterations in the endocrine

* Address of the chairman of the Section on Practice of Medicine read before the joint meeting of the Section on Practice of Medicine, the Section on Pharmacology and Therapeutics and the Section on Pathology and Physiology at the Seventy-Third Annual Session of the American Medical Association, St. Louis, May, 1922.

organs and with demonstrable physiologic or chemical evidences of overfunction or underfunction of those organs

Sufficient knowledge has been gained by these and other methods to make it seem clear that the incretions may act on distant cells in a modifying way either directly through transport through the blood to them, or indirectly through the intermediation of the autonomic nervous system When they act directly, they may determine the way in which the energies and substances in the terminal cells are utilized (functional correlation), or they may supply substances that are actually made a part of the distant cells that receive them and use them for their nutrition or for structural change (formative influence) When they act indirectly through the intermediation of the autonomic nervous system, they may, by stimulating, favoring or inhibiting the fibers of that system, greatly modify the functions of the secretory and excretory organs of the *body and of the involuntary musculature of the vascular*, digestive, respiratory and urogenital systems

Furthermore, either by direct stimulation of the nerve mechanisms concerned or by indirect influences on these mechanisms through the autonomic nervous system, endocrine products undoubtedly play an important role in the physiologic processes that are conceived of as running parallel to certain of the psychic functions, especially those that we designate as the affective and the conative This relationship of the incretions to the psychic mechanisms would seem clear from clinical observation of pathologic emotivity and of pathologic behavior observable in various endocrine disorders, notably in exophthalmic goiter and in myxedema

It is known, further, that profound effects are produced by certain of the incretions, especially those of the thyroid, the hypophysis and the gonads, through the regulation of the metabolic processes Whether these effects, in turn, result from influences exerted directly by the hormones on the body cells or indirectly through the mediation of the autonomic nervous system must be left to further investigations to reveal It would seem probable, however, that an acceleration of the general metabolism, such as can be induced by an excessive thyroxin production by the thyroid gland, may be due to a direct hormonal influence on the processes of combustion within the body cells, though it is conceivable that the same effects might be produced indirectly through hormonal action on a hypothetic metabolism-regulating center, located, say, in the interbrain Similarly, one might speculate regarding localized morphogenic effects, such as the growth of the acra in acromegaly, which could be due either to selective hormonal influences on local groups of distal cells concerned *in the growth processes, or to selective hormonal* influences on local groups of trophic neurons of the autonomic nervous system

THE SO-CALLED HORMONOPOIETIC SYSTEM

The conception that the endocrine organs are linked together so as to form a system of reciprocally dependent organs (hormonopoietic system) has gradually gained general credence, not only among clinicians, but also among physiologists and pathologists And it must be admitted that there is considerable evidence in favor of the existence of such a correlative interdependence among the several *incretory glands* Physiologists, through their experiments, have adduced many facts that point to manifold interrelationships between the glands of internal secretion And clinical-pathologic studies have shown that uniglandular endocrinopathies are rare, whereas pluriglandular endocrinopathies are common In exophthalmic goiter, for example, we see not only diffuse hyperplasia of the thyroid gland but also, not infrequently, hyperplasia of the thymus as well as signs of insufficiency of the gonads In Froehlich's syndrome, to cite another instance, we see not only the signs of a disorder of the hypophysis cerebri but also evidences of hypogenitalism It seems very probable therefore, that in the chemical integration of the bodily activities a certain cooperation among the endocrine organs is essential The hormonopoietic system is concerned as a whole It, like the nervous system, helps to correlate the partial systems of the body into a harmonious unity

EVOLUTIVE SIGNIFICANCE OF THE INCRETIONS

That the substances produced by the incretory organs are of great importance in the development of the individual, not only during embryonic life but also during the further evolution of the organism to the acme of its development, is now a generally accepted view The ontogeny of the single organism depends on reactions that occur between the germ plasm of the fertilized egg cell, on the one hand, and the environment (prenatal and postnatal) on the other The fertilized germ plasm, consisting of a complex of "gens," constitutes the so-called "genotype," which determines the modes of reaction that are manifested during development Environmental influences (at first chemical and physical, later on also psychic and social) are the other factors that are concerned in the development of the single creature The resultant of the interaction of these environmental influences on the one hand, and the inherited influences on the other, is the "realized organism," or, in the case of human beings the "realized person" This realized person is sometimes spoken of as the "phenotype" The inherited or constitutional factors (genotype) are known as the "determination factors" in development, whereas the conditioning influences of the environment are known as the "realization factors" (Roux) The part contributed by the germ plasm to the phenotype is known as the "constitution" of the individual, whereas the part contributed by the environment to the same phenotype is known as his "condition"

Students of heredity have long been interested in tracing the mode of development of the realized qualities or traits from their potentialities in the gens It now seems clear that, in this evolutive process, hormonal substances derived from the endocrine organs are of prime importance The functioning of the endocrine glands during development depends in part on their genotypic origin and in part on the modifying influences exerted on these glands at different stages of development from the environmental side It seems probable that a more exact understanding of racial peculiarities, of normal constitutional types or personal variants, and of pathologic anomalies of constitution will depend on our acquiring a more precise knowledge of endocrine activities during development

The general dimensions as well as the relative proportioning of the body are certainly in large part dependent on the incretions acting as morphogenic stimuli These stimuli determine not only the development of the skeleton and the closure of the epiphyseal

lines but also the development of the soft parts In a word, both the form relations and the functional manifestations of the phenotype are largely the result of endocrine activities The origin of the bodily features and a whole series of local and temporal maturations depend in the developing individual on a correlative differentiation that is largely determined by the functioning of the endocrine glands The special species characters, the special age characters, and the special sex characters of the realized person find their explanation here So, too, the strange faults of composition of the human body, the various bizarre anomalies of constitution that we see apparently owe their origin to endocrine disharmonies of the earlier developmental periods, disharmonies that are usually of genotypic origin, though they may sometimes, perhaps, be due to extraconstitutional, or so-called conditional, abnormalities

The task of the endocrinologist in unraveling the specific influences of the single endocrine glands on growth and development is one of extreme complexity, but nevertheless one in the solution of which gratifying progress is being made How far during intra-uterine life increlions derived from the mother (so-called "harmozones" of Gley) may reach the fetus and participate in morphogenesis (normal or pathologic) is a further task in which students of constitution and condition must sooner or later become interested

INVOLUTION AND ITS ENDOCRINE RELATIONSHIPS

After the body and the psyche reach their acme of development as the result of a long series of evolutive processes, a reverse process gradually sets in, both body and mind being subject, no matter how good the constitution or how favorable the environment, to gradual but progressive involution Physical and mental endurance lessen, the hairs grow gray or fall out, the skin becomes wrinkled, the teeth fall out, the stature lessens, the metabolic processes become retarded, interests change, desires begin to fail, and memory becomes uncertain In other words, the person "grows old" Coincident with the appearance of these involutive phenomena there seem to be changes not only in the endocrine glands themselves but also in the terminal organs on which their products operate In pathologic constitutions, in which the complex of gens in the genotype has been deficient, one or more of the involutive phenomena may prematurely appear Doubtless, too, persons of normal constitution who have been exposed over a prolonged period to very unfavorable environmental influences may become the victims of a precocious senium Some of the so-called heredofamilial diseases of the nervous system are probably examples of premature involutive processes affecting partial constituents of the organism, though how far, if at all, abnormal endocrine functions are responsible, we do not yet know Exact studies of the various processes of involution and their relations to the increlions will provide an abundance of work in the future for investigators of normal and pathologic physiology

CLINICAL RECOGNITION OF ENDOCRINE ABNORMALITIES

The clinical recognition of the endocrinopathies has been greatly aided by the observation of human beings in whom single glands have been removed surgically, have been severely traumatized, or have suffered destruction by disease The findings in human beings have been manifoldly corroborated by experiments on animals The studies of myxedema due to loss of the thyroid, of tetany due to loss of the parathyroids, of dystrophia adiposogenitalis due to injuries of the hypophysis, eunuchism due to loss of the gonads, of Addison's disease due to destruction of the suprarenals, and of diabetes mellitus due to injury to the islands of Langerhans, have thrown a flood of light on endocrine domains Studies of overfunction and of dysfunction have been similarly rewarding But various permutations and combinations of symptoms and signs that are possible in complex endocrinopathies make their study exceptionally difficult We are only on the threshold of that knowledge that we hope ultimately to possess

THERAPY OF THE ENDOCRINOPATHIES

Though the principles of therapy for the endocrine diseases are not hard to grasp, the application of these principles in practice is compulsorily restricted, owing to the fragmentary character of existing knowledge When, through constitutional deficits, or through unfavorable conditional influences, disharmonies of the hormonopoietic system arise, and evidences of hyperfunction, of hypofunction or of dysfunction, of one or more of the single endocrine organs appear, therapeutic intervention may become desirable Thus, in the various constitutional anomalies that seem to be dependent on endocrine imbalance, prophylactic measures may be undertaken with the object of maintaining the subjects of these anomalies within the limits of normal responsivity We attempt by adequate measures to counteract in such persons the special disposition to disease that the constitutional anomaly entails When a disease process has already developed, in other words, when an endocrinopathic personal variant has become incapable of satisfactory adaptation (state of irresponsivity), the physician may attempt to decrease function here, to increase function there, or to modify function elsewhere, in the hope of restoring balance, and of bringing the powers of personal adaptation again within the limits of normal responsivity Thus, in hyperfunction of an endocrine organ it may be desirable to excise a portion of it, or to curtail its activity by diminishing its blood supply (ice-bag, arterial ligation), or, by means of a depressive radiotherapy or chemotherapy On the other hand, in the case of hypofunction, it may become desirable to resort to organ transplantation, or to a substitution therapy (administration of gland substance, or of gland extracts, or of isolated hormones), or to attempt to revive a failing function by a dietetic hygienic regimen, or by mild stimulative radiotherapy

The field for endocrine therapy is undoubtedly a large one, but how most effectively to work in it, we must slowly and painstakingly ascertain Relatively little is gained, and much harm can be done, by reckless, ill-planned, fumbling attempts at increlory therapy Much better is it to proceed patiently, cautiously and methodically, rigidly controlling every step, and faithfully recording our failures as well as our successes Only slowly will it be possible to acquire the knowledge and the technic that will permit a physician properly to help the single endocrinopathic patient As yet we are far from being able satisfactorily to disentangle in a given person the complex interacting determination factors and conditioning factors that account for a given endocrinopathy Adequate disentanglement of these factors is, however, the goal toward which we must strive

SOME CONDITIONS CONTROLLING INTERNAL SECRETION*

W B CANNON, M D
BOSTON

No one may now question the great influence of the glands of internal secretion on important physiologic processes The growth of the body, the proper development of the nervous system, the appearance of secondary sex characters, the orderly sequences in the reproductive cycle, the nature and rate of chemical changes in the body—all these fundamental processes seem to be in the grip of the endocrine organs Agents which can determine whether an individual shall be a giant or a dwarf, an idiot or a normally intelligent person, a "sissy" or a real male, a bearded lady or a woman, agents which are essential to normal metabolism—*indeed, whose destruction may lead promptly to* death—must evidently be respected

There appears to be a tendency just now, however, to pay these glands not only respect, but reverence and homage and a blind worship The endocrine organs are referred to as "regulators of metabolism" and as "regulators of personality," as if they occupied an imperious position in our internal economy, and the other organs were mere servants to do their bidding This is a concept which is largely based, I believe, on the marked effects of either the destruction of endocrine glands or the development of tumors and other pathologic states within them When a gland is destroyed it is gone forever, and its absence tells us nothing about how it worked or the modulations of activity it may have had On the other hand, tumors *are* dictators in relation to the rest of the body, living riotously outside the law

Thus, two extreme conditions, neither of them normal nor even remotely physiologic, have led to the assumption of an endocrine almightiness Is that the mode of organization of the body? Is our internal government autocratically ruled by a czar or a kaiser or by groups of kings and princes, represented by the ductless glands, or is there a more democratic arrangement whereby influences pass to and fro among the various parts of the organization and, after many mutual adjustments, finally express themselves in function?

The physiologist regards the body in the latter sense —as a system of organs, each performing its service, each influenced by other organs and capable in turn of influencing other organs, and each having a use and a value only in relation to the others

Questions now arise regarding the real status of the glands of internal secretion If they have not the dominant position commonly assumed for them, how may they be subordinated? What influences can be brought to bear on them in such a way as to modify their activity? These are important questions to have answered—important because of the profound effects which the ductless glands themselves are capable of exerting In a brief survey I propose to present some of the evidence for physiologic control of the internal secretions

EVIDENCE FOR NERVOUS CONTROL

We now have evidence that at least the suprarenal medulla, the liver and the thyroid gland are subject to sympathetic nerve impulses Stimulation of the splanchnic nerves causes a discharge of epinephrin from the suprarenal glands into the blood stream in an amount which markedly affects other organs Such stimulation also liberates sugar from the liver Uridil and I[1] have shown that under stimulation the liver yields another substance which raises blood pressure and causes an acceleration of the denervated heart Furthermore, Smith and I[2] recently described experiments that confirm earlier work and testify to the efficacy of cervical sympathetic stimulation in calling forth a secretion from the thyroid gland

It is well known that the sympathetic division of the autonomic system is brought into action by pain, asphyxia and great emotional excitement That the *three endocrine organs mentioned above may* be strongly influenced by such conditions has been proved by numerous observations made both on experimental animals and in clinical cases Extra epinephrin circulating in the blood when a sensory nerve is stimulated or signs of rage are evoked can be demonstrated by a faster beat of the denervated heart[3] Emotional hyperglycemia or glycosuria, due doubtless to extra sugar freed from the liver, has been observed in cats disturbed by barking dogs, in students undergoing severe examination,[4] in aviators,[5] and in citizens terrorized by bombardments and air raids[6] The thyroid likewise may be stimulated by painful and asphyxial conditions Smith and I were able to obtain quite as striking results by such stimuli as we obtained by direct excitation of the cervical sympathetic strand The considerable *number of cases of exophthalmic goiter reported* as occurring in consequence of stressful circumstances during the war may perhaps be taken as additional indication of an influence on the thyroid gland exercised by the sympathetic nervous system

Another gland which may be affected by nerve impulses is the posterior lobe of the pituitary Weed Cushing and Jacobson[8] have reported that stimulation of the superior cervical sympathetic ganglion induces glycosuria (even though all nervous connections with the abdominal viscera have been severed), and that the result fails to occur if the posterior lobe of the pituitary has previously been removed In harmony with this result is Shamoff's testimony that the same stimulation induces, besides glycosuria, such diuresis as is induced by pituitary extract[9] The inference that a hormone is discharged *from the pituitary* as a result of stimulation has been somewhat invalidated by Rabens and Lifschitz,[10] who were unable to produce glycosuria by stimulating under physiologic conditions or to modify the glycosuria due to ether Furthermore, though Keeton and Becht[11] did augment the reducing substance in the blood by direct excitation of the pituitary, the effect was abolished by severance of the splanchnic nerves A nervous control of secretion from the posterior lobe of the pituitary is therefore in question

Thus far, attempts to prove that internal secretion of the pancreas is subject to sympathetic impulses have proved futile. Allen[12] has testified to his inability to secure any indication of such nervous control, and von Noorden[13] has declared that he has not seen any influence of the excitements of war in producing true diabetes. Indeed, in the Central Empires, where the food shortage was marked, the deaths from diabetes were fewer toward the end of the war, despite the increasing nervous stress, than they had been at the beginning.[14] According to de Corral,[15] however, stimulation of vagus fibers below the branches to the heart results in a reduction of the sugar content of the blood. This research, not yet confirmed, offers the only hint of which I am aware that the islet cells may be governed by nerves.

Nervous control of ductless glands involves the idea that they, like other structures governed by nerves, have their activities adapted to the needs of the body at different times. That the organism survives and lives normally when nerves to the suprarenal[16] or thyroid[17] gland are severed is not proof that the nerves are useless, any more than the continued service of the denervated heart as a pump is proof that the vagus and accelerator nerves are useless. The nerves may have, in relation to the glands, just as in relation to the heart, a tonic action for routine purposes, and at times of critical need they may have a special, or what I have called an "emergency" function, capable of rapidly mobilizing the bodily forces, internal secretions included, for the welfare of the organism as a whole.

No better illustration could be given of the tendency to regard the internal secretions as supreme and the nervous system as quite subordinate than in the theory underlying the clinical conceptions of vagotonia and sympathicotonia. Indeed, Eppinger and Hess,[18] the authors of the theory, have concluded that "the entire vegetative nervous system is under the control of the glands of internal secretion." Epinephrin is, indeed, able to reproduce almost all the changes that occur when sympathetic impulses are discharged. It has been supposed, therefore, to exercise a tonic action on sympathetic endings. For example, the height of arterial pressure is assumed to depend on the constant discharge of epinephrin into the blood stream, and a low blood pressure is ascribed to "hypo-adrenia." In order to have an antagonist for epinephrin—some substance which would take command of the opposing forces—Eppinger and Hess have conjured up a hypothetic hormone, "autonomin," acting like pilocarpin and physostigmin on the nerve endings of the cranial division of the automatic system. This assumed entity, first predicated in 1910, has never had the fortune of a real existence. Nevertheless, clinical literature has been rife with descriptions of cases with vagotonic and sympathicotonic dispositions.

It is well to recognize that there is no good evidence that epinephrin has any tonic effect in maintaining blood pressure. Aub[19] has measured the pressure four or five days after removal of both suprarenal glands and found it normal. Since epinephrin disappears from the blood a few minutes after it is injected or secreted, the continued normal pressure cannot be due to persistence of that substance in the blood. Stewart and Rogoff[16] have severed the nerves to one suprarenal gland and removed the other. Practically no demonstrable amount of epinephrin is secreted under such circumstances, and yet the animals remained for months in quite good condition. Gley and Quinquaud[20] have shown that vascular reflexes occur fully as effectively with the suprarenal glands absent as they do when the glands are present. Furthermore, Hoskins and McClure[21] pointed out, years ago, that an amount of epinephrin required to cause a rise of blood pressure is sufficient to stop all motions of the stomach and intestine. A ridiculous mechanism it would be that would stop digestion in order to provide a few extra millimeters of arterial tension! There is no satisfactory evidence that, in natural quiet existence, the suprarenal medulla gives off any secretion whatever. In times of stress it is brought into action by nerve impulses and may, indeed, then support the influence of the sympathetic system, and have besides special functions of its own.[22]

The general arrangement of the sympathetic division is favorable to diffuse and widespread action in which a distributed chemical agent could participate. The vagus endings and the endings of the other parts of the cranial autonomic division lie in or near the organs innervated, and are therefore favorable to separate and discriminating action. By means of the general diffuse action of the sympathetic, and the opposite particular action of the parts of the cranial autonomic supply, every variety of change is provided for. All the viscera can be affected simultaneously in one way or the other through increased or decreased tone of the sympathetic division. And any special organ can be separately affected one way or the other through increased or decreased tone in the special nerve of the opposed cranial division that is supplied directly to the organ. The sympathetic is like the soft and loud pedals, modulating all the notes together, the cranial autonomic is like the separate keys.

A dilated pupil, for example, due to increased sympathetic activity attending excitement, should be accompanied by a rapid heart rate, vasoconstriction, stoppage of the motions of the stomach and intestine, and other evidences of widespread sympathetic influences. Epinephrin secreted at the same time would act synergistically with the nerve impulses. On the other hand, constriction of the iris by action of the motor oculi when the light is strong may not be accompanied by disturbance of any other part of the cranial autonomic supply to the viscera. Indeed, there is no conceivable advantage in having a mechanism in which strong light would result not only in a smaller pupil, but also in a slower heart rate and an increased tone of the gastro-intestinal tract. As one can readily perceive, a single substance, "autonomin," acting extensively, like pilocarpin, on cranial autonomic endings, might have most disorderly effects in forcing to operate coincidently and in an unadapted manner organs whose functions in calm existence are not importantly related to one another.

The ill-based theory of vagotonia has almost no respectable evidence to support it Not only the criticism of laboratory workers but also the testimony of clinical observers has done much to discredit it Cases are cited in which patients are equally hypersensitive to epinephrin and pilocarpin,[23] in which pilocarpin, atropin and epinephrin produce practically identical effects on the blood,[24] in which both atropin and epinephrin will stop auricular fibrillation,[25] and in which careful studies on various bodily functions showed no consistent sensitization to either the "sympathicotonic" or the "vagotonic" drugs In the presence of the foregoing evidence, "vagotonia" becomes merely a name—a name which, as applied to the entire cranial autonomic division and presupposing a general reinforcing and vagotonic hormone, is wholly without meaning

Reference was made above to the fact that activity of the sympathetic system may be varied up or down Strong stimulation of an afferent nerve will cause vasoconstriction and other indications of diffuse sympathetic discharge, including suprarenal secretion On the other hand, stimulation of the central end of the depressor nerve will cause vasodilation and a checking of any suprarenal secretion which may be going on[26] Quite possibly, therefore, conditions may exist in the body, characterized by either greater or less sympathetic tone than normal, but such states would not be determined by independent dominance of suprarenal secretion, for, as shown above, lack of any secretion at all does not lessen the efficacy of sympathetic impulses, and extra secretion is ordinarily dependent on the effect of nerve impulses The condition of the nervous system, not of the suprarenal medulla, therefore, is of primary moment

In the foregoing review, evidence has been adduced to show the subjection of certain endocrine glands to nervous government This emphasis, however, should not be interpreted as implying an independent dominance of the nervous system, for it, like other systems, is conditioned in its activities Again I wish to lay stress on the fact that the body is an organism, and that the parts collaborate and exercise mutual influences on one another

EVIDENCE FOR HUMORAL CONTROL

Nerves have been described as present in other of the endocrine glands than those mentioned above—for example in the anterior lobe of the pituitary body[27] and in the parathyroid bodies[28] On the other hand, it is reported that no nerve fibers are distributed to the interstitial cells of the testis, and very few to the suprarenal cortex Nevertheless, both these structures may undergo hyperplasia, associated, at least in the case of the interstitial tissue, with seasonal depression at times of sex activity[29] Evidently some other mode of control besides nerve impulses must prevail in such conditions And since the blood stream alone brings the glands into relation with other parts, it is naturally assumed that the influences affecting the glands and passing away from them are conveyed in the circulating blood In other words, the influences are of the humoral type

The presence of a nervous control of internal secretion does not preclude a humoral control Thus, the heart and the stomach and intestine are readily influenced by nerve impulses But they are likewise affected by epinephrin discharged by the suprarenals, i e, by a humoral agent Also the thyroid, though subject to nerve stimulation, is responsive to chemical factors brought by the blood For example, Cattell and I[30] found some years ago that stimulation of a discharge from the suprarenal medulla would cause an electrical action current in the thyroid

When we begin to consider the evidence for interrelation of the ductless glands, we find ourselves in a maze of complex possibilities, contradictory reports and uncertain inferences Much of the evidence is derived from distant effects of ablation or destruction of one or more of the glands, or from changes due to tumor growth, or to feeding gland substance None of these circumstances can be regarded as physiologic The results may be suggestive of some relation between the gland removed, or abnormal, or fed, and the other gland or glands which are altered thereby But it is hazardous to draw inferences from pathologic states relative to physiologic processes And even if there is *some* relation, we have not made satisfactory progress until we know what the relation is, the way it works and its full significance If we knew nothing of the function of the heart and as much as we now know about the endocrine organs, we might be led to infer that the semilunar valves exercise an inhibitory influence on the growth of the heart, for does not destruction or injury of the valves result in an enlargement of that organ? Do we reason any better than this in many of our inferences from the effects of experimental removal of the endocrine organs? We know almost nothing, for example, about the normal functioning of the suprarenal cortex Several observers have confirmed Hoskins'[31] observation that feeding thyroid gland enlarges the suprarenal body, especially the cortical portion, according to Herring[32] It is reported to be enlarged also by starvation[33] or by a diet deficient in vitamins[34] And Gley[35] and also Carlson[36] have found enlargement of the suprarenal bodies after removing the thyroid glands Is the enlargement due to stimulation by the thyroid, or is it compensatory to increased metabolism, or is it a biologic response conservative of important bodily material when the supply is low or is being rapidly consumed? These are some of the possibilities Certainly, in the presence of these complexities one has no clear idea of thyroid influence on suprarenal function

Possibly too much emphasis has been laid on mere changes of size More than thirty years ago, Rogowitsch[37] first noted that thyroidectomy is followed by hypertrophy of the pituitary body This observation has been confirmed by numerous investigators Kamo,[38] who removed the thyroid from young dogs, found, after a few months, marked pituitary enlargement, even to more than twice the normal size, manifested chiefly in the anterior lobe We commonly associate hypertrophy with extra activity, and we have

evidence that extra activity of the anterior lobe of the pituitary body is attended by an overgrowth of the skeleton Animals deprived of the thyroid, however, are stunted in growth Here we have an instance of hypertrophic change in one gland induced by removal of another, but with no corresponding hyperfunctional effect

Perhaps we shall have clearer signs of the cooperation of the endocrine organs if we consider briefly the influence of various representative glands on a common function For illustrative purposes I propose to call attention to some of the effects of the glands on certain bodily processes, which were mentioned earlier —growth, reproduction and metabolism

The relation between overgrowth of the skeleton, as in gigantism and acromegaly, and hyperplasia of the anterior lobe of the pituitary, is now fairly well established Extra skeletal growth is also associated with early castration On the other hand, both clinical and experimental studies point to early pituitary deficiency as causing failure of bony development This form of dwarfism is characterized by both short and slender bones A third gland whose function is essential to growth is the thyroid, for in its absence the stature is stunted Here are three endocrine organs, all having marked influence on the attainment of normal size One could readily speculate as to how they influence one another—the pituitary and thyroid appearing to work cooperatively and the gonads acting as a check on them—but we need facts rather than speculation

Reproduction depends on the gonads, of course, but it also depends on the thyroid and the pituitary glands If the young animal is deprived of either the thyroid or the pituitary, the generative organs are only slowly or imperfectly developed, so that a condition of sexual infantilism persists Hyperplasia of the pituitary, and also of the suprarenal cortex, in the young, is sometimes associated with precocious sexual maturity and activity Both the thyroid and the suprarenal cortex become enlarged during pregnancy Thus, the evidence seems to point to the thyroid and the pituitary glands and to the suprarenal cortex as factors essential to proper establishment of the reproductive function, and also possibly collaborating in the female, in the performance of that function

The pancreas, the suprarenals and the liver primarily, and likewise the thyroid and the pituitary, are all concerned with carbohydrate metabolism As is well known, excision of the pancreas results in diabetes, stimulation of the liver or injection of epinephrin increases the sugar in the blood, and removal of either the thyroid or the pituitary raises the assimilation limit of sugar Diabetes is occasionally associated with acromegaly and with exophthalmic goiter Probably all five of the glands mentioned above either cooperate or form a fairly stable combination of opposed influences But, again, how these organs are interrelated in their effects on metabolic processes is not at all clear

In the foregoing paragraphs I have merely hinted at some of the signs of cooperation among certain endocrine glands My purpose in doing so was to make the point that here, just as in the nervous government of internal secretion, there are indications that we are dealing with arrangements which are normally well ordered and subject to automatic control Bodily functions are managed by a system of checks and balances—by mutual adjustments such as those between antagonistic muscles, and by maintained equilibria, such as those between material income and outgo, and between acid and base in the blood We are justified by what we already know of bodily organization in looking for similar modes of restraining and releasing the internal secretions If the endocrine glands are regarded as the regulators of important physiologic processes, normally they are well regulated regulators Much work must still be done, however, before we shall know the mechanisms whereby the control of these agents is exercised But the work is highly important because of the potency of the endocrine organs when they are deficient or when they escape control and through pathologic activity play havoc with our internal adjustments

---

THE RELATION OF THE INTERNAL SECRETIONS TO METABOLISM*

JOSEPH C AUB, M D
BOSTON

Among the various functions ascribed to the glands of internal secretion, the regulation of metabolism ranks high Not only is it a very important part of their activity but it is also the function about which the greatest and most accurate knowledge has been accumulated Of course, the general regulation of metabolism is not wholly controlled by the glands of internal secretion, for there are many other factors which exert influences which cannot now be ascribed to the activity of these glands Examples are found in the effect of exercise, the specific dynamic action of foodstuffs, fasting, sleep, etc, and it therefore cannot be assumed that these endocrine glands absolutely control the rate of metabolism But there can be no doubt that their general influence is great

As far as our knowledge goes, this influence is largely exercised on the heat production as a whole rather than on individual components of metabolism, such as the carbohydrates or salt This is not true of all of the glands The pancreas has a differential action and exerts its regulatory effect largely upon the utilization of carbohydrate It is also possible that the parathyroids have some isolated influence on the metabolism of inorganic salts [1] It is also true that the metabolic effects of other glands may be developed predominantly from one foodstuff, as in the combustion of carbohydrate after the administration of epinephrin, [2] but, in general, apart from the action of the pancreas and the parathyroids, the effect on the total rate is a fairly good index of the general influence of the glands on the body metabolism, at least as far as we know

The effect of each gland on the metabolic rate has been the subject of considerable recent investigation, so that a short summary of the work is difficult It is probably true that many glands credited with various effects produce these effects by indirect reactions on other glands, so that they are really merely indications of interrelationships The problem of interrelationships among these endocrine glands is difficult and

should be discussed only when based on careful experimental data It is with this point of view in mind that I shall undertake, first, to show that probably only two glands, the thyroid and the suprarenals, are fundamentally and chiefly involved in the regulation of the total metabolic equilibrium, and, second, to suggest the mechanism of their action as fully as present knowledge will permit

A summary of the literature discloses the fact that there are four glands to which are attributed an influence on the rate of metabolism [3] Of these, the thyroid gland stands preeminent, and its stimulating action is so well known that further discussion is not essential here The gonads are also a factor, although a minor one Their removal is followed, after a period of about three weeks, by a fall in metabolism, as has been shown by Loewy and Richter,[4] Luethje,[5] Murlin [6] and others Korenchevski,[7] taking the data of his pupil Rovinski,[8] showed that this fall of metabolism after castration largely disappeared if the thyroid gland was first removed He therefore concluded that the effect of the gonads on metabolism was accomplished through an interrelation with the thyroid gland, and that the lowered metabolism following castration was due to a depression of thyroid secretion rather than directly to absence of the gonads

The influence exerted by the anterior pituitary is similar to that of the gonads, in that, after extirpation, there is a gradual reduction of the basal metabolic rate This was first shown by Benedict and Homans [9] Sometimes one finds, clinically, changes in the rate of metabolism of patients with active disease of the pituitary, but this is not a constant finding Boothby has recently stated (at the Society of Clinical Investigation) that, in his experience, these changes in acromegalias were always found in those patients who also showed some thyroid involvement It is therefore possible, although it has not been finally proved, that the metabolic effects of the pituitary are accomplished through the thyroid just as, probably, in the case of the gonads Administration of the glandular products of these two, however, has not affected the metabolism consistently, and further work needs to be done along these lines

The fourth organ which regulates the metabolism is the suprarenal This is a recent discovery Most of the work on this subject has been of a pharmacologic nature, by the subcutaneous and intravenous injection of large doses of epinephrin, as in the experiments of Tompkins, Sturgis and Wearn,[10] Sandiford [11] and others Their results have shown that there is an invariable rise of metabolism, which develops and disappears within a period of minutes Boothby and Sandiford showed that this could not be explained by a mere mobilization of glucose [2] These pharmacologic observations suggested that the secretions of the suprarenal glands, as they occur physiologically, might play a role in the regulation of metabolism, and Miss Bright, Dr Forman, Dr Uridil and I [12] have studied this possibility We found that removal under ether anesthesia of the suprarenal glands of cats was followed by a rapid reduction of the metabolic rate This occurred while the animal was still in good condition, and persisted until the final collapse

At the meeting at which these experiments were reported, Marine [13] announced his results with rabbits he laid stress on a belated and temporary increase in metabolism, which he has subsequently [14] interpreted as due to secondary thyroid activity We have not investigated the transient rise in metabolism which he reports but we have studied the fall of metabolism obtained so definitely in cats It was found that if the suprarenal glands were removed under urethane anesthesia, the fall in metabolism appeared shortly and tended to progress In these experiments, the cat remained in an anesthetized condition throughout the entire observation The observed fall in metabolism was not affected by injections of extracts of the suprarenal cortex, but could be eliminated by intravenous injection of epinephrin administered at a rate which is said to be physiologically probable in life, according to Stewart and Rogoff,[15] and Cannon [16] This has recently been confirmed by Boothby and Sandiford [17] in the dog with intact suprarenals Such results are certainly good evidence that the suprarenal glands may play a part in the variation of the metabolic rate by means of the normal secretion of epinephrin Clinical evidence for this is not so readily found, but it is probably seen in the high metabolic rates often found in the first observations made on excited patients It is not rare to find an untrained nervous subject who is emotionally disturbed by the procedure of the test Such patients may then show a higher metabolic rate than they display later, even though they remain quiet According to the emergency theory of Cannon,[18] it is during such excitement that epinephrin would be secreted In the few cases of Addison's disease reported with metabolic studies, evidence of reduced metabolism has been shown either by the nitrogen elimination or by the basal metabolic rate, but these cases are still too few to generalize about

Are the metabolic effects of thyroxin and epinephrin independent? Marine [19] has shown that the increase

of metabolism which follows the injection of epinephrin may be obtained in animals which have been previously deprived of their thyroid glands Similarly, we have shown that the reduced metabolic rate following suprarenalectomy under urethane and the stimulating effects of epinephrin when it is injected at a physiologic rate are demonstrable in animals either with or without the thyroid gland It is therefore clear that the thyroid gland is not an essential factor in the action of epinephrin on metabolism That the converse of this is true, that the suprarenal glands are not essential for the continued stimulation of metabolism by thyroxin, may be shown in the following manner The metabolic rate is raised above normal by the injection of thyroxin If the suprarenal glands are now removed, the metabolic rate does not fall to normal but is maintained at a high level for many hours, so that the high metabolic rate in hyperthyroidism is not dependent on the presence of the suprarenal gland or its secretions It is therefore fair to assume that the calorigenetic effects of thyroxin and epinephrin are distinct and not interdependent The time relations of their actions also differ distinctly Studies at the Mayo Clinic first revealed that the metabolic effects of the injection of thyroxin are manifest only after many hours and last for days Epinephrin, on the contrary, produces effects within minutes, not hours, and likewise loses its influence after a brief period All these facts have led me to the theory that there is a double endocrine mechanism for regulating the metabolic rate, that some of the acute fluctuations of basal metabolism may be ascribed to the influence of the suprarenal glands, and that the thyroid is more sluggish, but probably more important in its regulatory action [12] Such a mechanism would be analogous to the control of the acid-base equilibrium of the blood as demonstrated by L J Henderson, in which the lungs and kidneys share the burden, the lungs making the necessary immediate adjustments by the excretion of carbon dioxid, the kidneys, acting more sluggishly, by the excretion of phosphates

What is known about the way in which these hormones accomplish their metabolic effects? This is a field in which further investigation is needed Most work has been directed to determining the nature of the metabolic effects rather than to determining how they are accomplished But we do know some facts Thus it has been found by Lovatt Evans [20] that epinephrin will stimulate the isolated heart to more rapid contractions and to a markedly increased metabolism Recently, Martin and Armitstead have shown [21] that an isolated resting muscle has a higher metabolism, as denoted by acid production, when in the presence of epinephrin than when no epinephrin is present These two experiments point to the action of epinephrin as a direct one, capable of influencing metabolism by affecting peripheral muscle tissue directly, as Boothby suggested There is apparently no need of the central nervous system or of other internal secretions as accessories to its stimulating action, but it must work as a direct metabolic stimulant either on the nerve end plates or on the muscle cells themselves

No such clear evidence exists however, in support of the theory that the thyroid acts on cells by stimulating them directly to increased heat production It is, of course, a more difficult problem because there is so long a latent period before thyroxin manifests its effects, so that no rapid experiments can be made One might determine the metabolism of an isolated muscle then make the animal thyrotoxic and determine the metabolism of the opposite corresponding muscle This has not yet been done, so far as I know, so that the actual method by which the thyroid secretion stimulates metabolism is not yet known

The acute effects of a thyroid preparation on the isolated heart were studied by Richardson,[22] and later by Kakehi [22] in Asher's laboratory They could see no prompt effect from the presence of the thyroid alone on either the amplitude or the rate of the heart beat, but they did not study the metabolism It is probable that no immediate effect would be elicited, however, because of the latent period in the metabolic action of the thyroid Therefore, the theory of the general action of thyroxin directly on cells still needs an experimental basis We have, however, been able to study the metabolic effects of hyperthyroidism, particularly in regard to the roles played by activity, tremor and muscle tonus

Marie Krogh,[23] in a preliminary report published some years ago, suggested that muscle tonus might be the factor in the increased metabolism, and many have often thought, I am sure, that the striking evidences of muscular activity might explain the high metabolism in thyroid disease We studied animals rendered thyrotoxic by the injection of thyroxin Their metabolism rose in a few days to a level usually more than 50 per cent above their previous basal values When urethane anesthesia was then induced, and the metabolic rate again determined, it was found that the level remained high in spite of the fact that there was no muscle tremor and no activity other than cardiorespiratory movements If now the nerves to the limbs were cut the possibility of any tonus arising from either myelinated or sympathetic nerves was practically eliminated Even this procedure did not cause the metabolism to return to its original level It is therefore quite clear that neither activity nor muscle tremors nor muscle tonus explains the high metabolism found in hyperthyroidism

To show how fundamental are the metabolic effects of these two internal secretions, it is interesting to note, here that they may still be found under urethane anesthesia, although the metabolic stimulation from caffein or amino-acids has then disappeared [24] What the significance of this difference is, however, cannot be analyzed at present And so we return to the conclusion, often suggested, that the effects of both epinephrin and thyroxin on the metabolism are probably similar to that of increasing the draft under a fire This is fairly clearly established for epinephrin, but needs further evidence for the action of thyroxin It is true that the evidence brought forward in this paper has related largely to the two active substances which have been isolated from the thyroid and the suprarenals They probably have at least one more secretion that derived from the suprarenal cortex Extracts from it have had no acute effects on metabolism in our

hands, and its function remains mysterious, although essential to life Whether it, too, has a metabolic function remains to be proved

CONCLUSIONS

1 Apparently, the two glands which most influence the total metabolism are the thyroid and the suprarenal (probably by epinephrin)

2 The mechanism of their actions are independent Collected evidence shows that the calorigenetic action of thyroxin is manifest without the suprarenals, that of epinephrin is present without the thyroids

3 The theory is advanced that the suprarenals exert acute effects, while the thyroid is the more sluggish regulator of the metabolic rate

4 The method of action of thyroxin and epinephrin on the body tissues has been discussed

---

HYPOFUNCTION AND HYPERFUNCTION OF THE DUCTLESS GLANDS*

A J CARLSON PH D M D
CHICAGO

It is difficult, if not impossible, to present the subject of endocrine dysfunction in a brief article, without appearing to be both ignorant and dogmatic, ignorant of many alleged facts, because time does not permit giving the reasons for their rejection, and dogmatic because practically every statement made in regard to the ductless glands today requires qualification, which is, for the most part, ruled out by the time limit Furthermore, I take part in this discussion with the diffidence of a man whose personal experience is limited largely to the experimental side of the subject However, I have a fair acquaintance with the entire endocrine literature, in both the field of science and the field of fiction, and I take for granted that we all subscribe to the principle that the rules of evidence or criteria for facts are the same in the experimental and in the clinical fields

HYPOFUNCTION

When the ductless glands are so situated that they can be surgically extirpated, in whole or in part, without injury to important adjacent organs, the extirpation of these glands in the healthy animal gives us the most reliable information regarding the results of hypofunction of each specific system The hypofunction syndrome may be complex and may gradually involve endocrine organs other than those extirpated, but the initial cause can with certainty be referred to absence of the function normally carried out by the organ which has been removed This ideal anatomic condition obtains in the case of the thyroids, the parathyroids, the pancreas, the thymus, the ovaries and the testes In most animals, the cortex and medulla of the suprarenal glands are so closely fused that it is difficult to extirpate the one without grave injury to the other This applies also to the two (or three) systems that make up the pituitary gland Furthermore, the location of the pituitary and the pineal glands within the cranial cavity and close to the midbrain renders it difficult to extirpate these organs without injury to the base of the brain, and tumors or cysts in these glands practically always involve brain injury by pressure

Extirpation experiments in healthy animals have thus established the following general facts

Loss of the thyroid is followed by cretinism in the young and myxedema in the adult But it should be noted that some of the myxedema symptoms following hypothyroidism in man are not readily produced even by complete thyroidectomy in the healthy adult animal

Loss of the parathyroids induces depression, tetany and death in a few days, unless the animal is subjected to special dietary and diuretic control

Loss of the pancreas leads to absolute diabetes and death from diabetes (in the dog) in from four to seven weeks

Loss of the testes is followed by persistent sexual infantilism in the young, and in the adult by loss of the sex urge and sex functions, and by gradual atrophy of most of the secondary sex characters

Loss of the ovaries results in persistent sex infantilism in the young and in premature menopause and gradual atrophy of most of the secondary sex characters in the adult

Loss of the suprarenal medulla induces no symptoms and no disease, according to the most reliable observations

Loss of the suprarenal cortex causes profound prostration and death within a few days, in what appears to be acute Addison's disease

Loss of the posterior lobe of the pituitary gland appears to produce no definite symptoms There are competent investigators claiming that this lesion induces diabetes insipidus and disturbance of metabolism while equally good workers hold that diabetes insipidus is caused by injuries to the base of the brain outside the hypophysis The question is not settled

Loss of the anterior lobe of the pituitary gland appears to produce impairment of growth and infantilism in the young, and in the adult a tendency to adiposity and somnolence, with atrophy of the gonads and failure of sex functions According to one group of investigators, complete extirpation of the anterior lobe leads to death, in profound depression in a few days, while another group of equally competent men claim that such deaths are due, not to the loss of the gland, but to injury to the base of the brain This question is open But all workers are agreed that almost complete loss of the anterior lobe (including unavoidable injuries to the base of the brain) leads to hypopituitary infantilism, at least in a percentage of the animals so operated on

Extirpation of the pineal gland causes no symptoms The loss of the spleen or the duodenum is also without endocrine effects Extirpation of the thymus produces no effect, except perhaps slight hastening of adolescence in the young

Time does not permit a further analysis of the hypofunction syndromes just outlined The hypothyroid and the hypopituitary syndromes are particularly difficult to evaluate or diagnose because of the variability of some of their major elements We must, therefore, clearly recognize that while the terms cretinism, myxedema or hypopituitary infantilism are permissible and useful in relation to primary etiology, these terms cannot be used as formulas representing facts established, and hence as a certain basis for therapy A cynical judge once asked, "What is truth?" but did not tarry for an answer The question, What is hypothyroidism or hypopituitarism may be laughed out of

* Read before the joint meeting of the Section on Practice of Medicine the Section on Pharmacology and Therapeutics and the Section on Pathology and Physiology at the Seventy Third Annual Session of the American Medical Association St Louis May 1922

court as "academic," or as already settled by this audience of "practical men", but I raise it nevertheless as a challenge to those who would sacrifice honesty for short cuts to commercial success, and those who would practice the trade of the quack under the protecting cloak of membership in an honorable profession

These extirpation experiments on healthy animals, from embryos to adults, permit the following generalizations

1 Each system of ductless glands appears to be essentially identical in function in all classes of vertebrates This fact renders it highly probable that corresponding glandular hypofunctions in man will induce similar syndromes We know that this is the case in regard to the gonads, from the effects of gonadectomy in healthy men and women

2 None of the ductless glands appear to work to full capacity under normal conditions, since from three quarters to seven eighths of each gland system may be removed in the healthy animal without producing any deficiency symptoms This is a very disturbing factor in the clinical field when we attempt to relate the histopathology of the ductless glands to the patient's disease

3 No matter what changes in the way of atrophy or hypertrophy may be induced in the remaining ductless glands on extirpation of any one gland system the essential effects following distinct hypofunction of each gland system appears to be specific for that system In other words, extirpation experiments on healthy animals afford little or no evidence of substitution or vicarious functioning by the ductless glands that remain in the animal

4 The symptoms produced by the extirpation of the ductless glands in healthy animals can be interpreted either on the hormone theory or on the detoxication theory

5 No chemical methods are at present available by which we can demonstrate the presence of hormones and their quantitative variations in the blood and tissues, or even in the glands themselves The iodin in the thyroid appears to be somewhat of an index of the thyroid secretion We can make iodin determinations of the blood, the lymph, and the other tissues of the body, but we cannot conclude that the iodin found represents thyroidin and this only We have chemical tests for epinephrin but epinephrin is probably not a hormone

In regard to the possibility that some, if not all of the ductless glands may work on the principle of detoxication, it is equally true that we have no chemical tests for the toxins in the blood and tissues that may be responsible for the hypofunction syndromes except possibly in the case of the parathyroids Recent work seems to demonstrate that the tetany and death following extirpation of the parathyroids are due to toxic protein derivatives produced by the action of the colon group of organisms on the animal proteins of the food Some of these toxic protein derivatives can be chemically isolated The foregoing facts may be stated positively by saying that so far, the tests for hypofunction of the ductless glands are indirect or biologic

6 The relative immunity of some individuals to complete or nearly complete extirpation of some of the ductless glands is usually explained by the age factor (the young being less immune) and by abberrant or accessory glandules That accessory glandules of some of the systems frequently occur is well known, but we question the adequacy of these explanations for all the exceptions

In the clinical field, results fairly comparable to those following extirpation of endocrine systems in healthy animals are produced by clearly destructive lesions in single gland systems Such lesions as tuberculosis cystic degeneration fibrosis, or atrophy, when including all or nearly all of the glands, are practically equivalent to extirpation with the knife, provided the lesions are strictly localized Such strict limitations of destructive lesions are rarely found in postmortems, especially in persons past from 30 to 40 years, but when they are established, we have what may be called frank hypofunction, and the etiology of the syndrome is just as clear as in total or partial extirpation of a one gland system in healthy animals In this way, the combination of careful clinical observations and postmortem studies have proved that hypothyroidosis and athyroidosis lead to cretinism and myxedema, that total or nearly total destruction of the suprarenal cortex leads to Addison's disease and death, that sufficient cystic degeneration of the hypophysis is followed by infantilism and that marked destruction of the pancreas induces diabetes Castration and spaying produces the same effects in man as in experimental animals with the additional factors of nervous disturbances of the menopause and, probably, in some males purely subjective effects in the way of feelings of regret or melancholia

There is no reliable evidence that hypofunction of the suprarenal medulla induces deficiency symptoms The theory of "suprarenalemia" as a clinical entity or disease is an illustration of where mere logic may lead us when the major premise is an error

The foregoing clinical conditions may be designated as frank hypofunctions of the ductless glands, and when the gland lesions approach complete destruction or atrophy, diagnosis can usually be made with a fair degree of certainty I make this statement with a good deal of hesitation, particularly in connection with the thyroid and the hypophysis Most of us have accepted as demonstrated facts the view that the thyroid secretion has a direct stimulating action on the basal metabolism, and that increase or decrease of the thyroid secretion in the body can be demonstrated by changes in the metabolic rate, at least as early and as clearly as any of the other changes in body functions that are supposed to be due to quantitative changes in the thyroid secretion But now come apparently reliable clinical reports to the effect that (1) so-called hyperthyroidism or toxic goiter may be present with a normal metabolic rate, and (2) hypothyroidism or myxedema may be present and parallel with a high a low or a normal basal metabolism If these are facts it is clear that the present basal conceptions of thyroid physiology must be revised But first let us make sure that these new observations are really facts And in the meantime, let us be still more careful in the diagnosis of clinical hypothyroidism and hyperthyroidism

If our foundation is so shaky in clinical cases of what appears to be frank hypofunction of the ductless glands, what can we expect in only slight degrees of hypofunction? Here we have no aid from the macroscopic and microscopic conditions or chemical analysis of the glands, as such conditions are chronic rather than speedily fatal, and even when the glands or part of a gland is available for study, the interpretation of the histologic findings is mostly conjecture

The other serious difficulty in the recognition of slight degrees of endocrine hypofunction is the fact that, in the case of some of the endocrine systems, the hypofunction must be considerable before the syndrome becomes clearly specific. This applies particularly to most of the nervous manifestations of endocrine hypofunction. Slight nervous disorders, slight gastro-intestinal disorders, slight disorders of metabolism, slight disorders of the sex life, seem to be produced by conditions in which evidence for primary endocrine etiology is lacking.

ALLEGED ENDOCRINE HYPERFUNCTION

The question of endocrine hyperfunction is not of as great importance in medicine as that of hypofunction, in view of our present knowledge. Hyperfunction must, of course, be considered in connection with the alternative theory of dysfunction or toxic secretion. The question of hyperfunction has no meaning or application in glands that work by detoxication.

1. Spontaneous endocrine hyperfunction is unknown in experimental animals. Much work has been done in the attempt to produce experimental hyperthyroidism in animals by thyroid feeding. Large doses of thyroid extract produce some of the symptoms of toxic goiter, such as increased metabolism, tachycardia, emaciation and gastro-intestinal disturbances. The nervous and ocular manifestations of toxic goiter are not produced.

2. In man, endocrine hyperfunction is assumed by many people as a causative factor in

(1) *Toxic goiter (the thyroids)*, (2) *acromegaly* (the hypophysis, anterior lobe), (3) hypertension (the suprarenal medulla and the thyroids), (4) precocious puberty (the suprarenal cortex, the hypophysis and the pineal gland), (5) diabetes (the thyroid), (6) excessive sex urge (the gonads), (7) excessive menstruation (the ovaries or the corpus luteum).

Now, what are the facts? In the first place, mere increase in the size of glands, mere hyperplasia, does not mean more gland activity or more secretion. We have thyroid hyperplasia and thyroid adenomas without physiologic disturbances, yet the size, structure and chemistry of the thyroid appear identical to these facts in toxic goiter. Biologic and chemical tests of the blood at present are not delicate enough to detect the thyroid secretion or quantitative variations of the secretion. The colloid and iodin of the thyroid is usually reduced in toxic goiter, but this is also the case in thyroid hyperplasia associated with no toxic symptoms. Furthermore, the reduced quantity of iodin, thyroglobulin or thyroxin in the gland may mean that the gland is producing more secretion, it may also mean that the gland produces less secretion. It is a fact that excessive thyroid feeding induces in man some of the symptoms of toxic goiter. Apart from this, the results of medical and surgical management of toxic goiter can be equally well explained on the basis of a toxic or perverted secretion. This theory, moreover, is not inconsistent with the existence of myxedema and toxic goiter symptoms in one person at the same time. This condition is difficult, if not impossible, to explain on the theory of hypersecretion. The primary relation of exophthalmic goiter to the thyroid may not be cleared up until complete thyroidectomy is made in a well controlled series of patients having toxic goiter. I believe this can be done without harm to the patient, if one or two parathyroids are spared or the parathyroprival symptoms are controlled by diet and diuresis and possible myxedema controlled by thyroid feeding. There are plenty of patients with toxic goiter showing little or no improvement on either surgical, roentgen-ray or medical therapy. Such patients would probably be better off with some myxedema than with severe exophthalmic goiter, and the medical profession would have taken a step forward through knowing with certainty the primary relation of the thyroid to toxic goiter.

We encounter similar difficulties in the relation of pituitary hyperplasias and tumors to acromegaly. We know for a fact that hypophysial adenomas or hyperplasias are associated with acromegaly, just as thyroid hyperplasias are associated with exophthalmic goiter. But the causal connection between the gland enlargement and the disease is obscured by the fact that we have hypophysial hyperplasias and tumors with acromegaly, and acromegaly without tumors of the hypophysis. Nothing resembling acromegaly has so far been produced experimentally by administration of hypophysial preparations. And the final difficulty is the condition of unilateral acromegaly, a fact that appears irreconcilable with the simple excess hormone theory of causation.

We may now ask whether any of the disorders of the sex life have been found to be due to hyperfunction of the gonads? If we could uncover the processes of life by logic alone, we might conclude that, since gonadectomy or frank gonad hypofunction decreases or abolishes nearly all manifestations of sex, excessive manifestation of the sex urge, of menstruation and of the nervous activities more or less specific for sex life are due to hyperfunction of the gonads. There is little or no support for such a conclusion from either the clinic or the laboratory. It is true that ovariectomy will stop menorrhagia, just as it will stop normal menstruation. Does that prove that menorrhagia is caused by ovarian hypersecretion? Not at all. The menstrual disturbance is just as readily explained by the action of qualitatively and quantitatively normal ovarian hormones on mechanism rendered hypersensitive by other factors. Given otherwise normal men and women, a hundred ovaries and a hundred testes instead of two would probably not increase the menstruation or the sex urge above the normal.

The question of toxic ovarian secretion has been raised in connection with osteomalacia. We have reports of cure of this malady by ovariectomy, also reports of failure of cure by ovariectomy. It is an open question. There is no evidence that the normal ovarian hormones have any special influence on the health of the bones.

The question of hyperfunction has also come up in connection with hyperplasia of the thymus, and with tumors of the pineal gland. Since extirpation of these glands produces no effect, it is difficult to conceive just how hyperactivity of the glands might cause disease, especially if the thymus gland works by the method of detoxication. Pineal tumors might cause far reaching effects by mechanical pressure on the midbrain.

ALLEGED HYPO-ACTIVITY AND HYPERACTIVITY OF THE DUCTLESS GLANDS THROUGH DISTURBANCE OF THE NERVOUS SYSTEM

We have the following possibilities. 1. The endocrine glands may be under complete control of secretory nerves, like the salivary and the lacrimal glands, in which case we would expect hypofunction and atrophy to follow denervation. 2. They may have no secretory

nerves, but may be controlled by the composition of the blood, as the kidneys are In this case, the effect of denervation cannot be predicted There may be hyperactivity, hypo-activity or no change in activity 3 They may be controlled in part by secretory nerves, in part by the composition of the blood like the glands of the stomach In this case also the effects of denervation might be zero These appear to be the facts

1 Sectioning of all the nerves to the ductless glands produces no demonstrable effect on the body functions, and no significant changes in the glands The suprarenal medulla seems to constitute an exception to the second part of this statement Denervation of the suprarenals induces no disturbance of body functions, except in the output of epinephrin This is decreased or completely stopped This shows that the output of epinephrin is under the control of vasomotor or true secretory nerves It also shows that epinephrin is of little or no importance as a hormone

2 Vasomotor nerves appear to be present in all the endocrine glands, and by histologic methods nerve filaments have been traced to or in close proximity to the gland cells themselves In some of the glands, notably the pancreas, numerous ganglion cells are present in the peripheral nerve net The suprarenal medulla, the posterior lobe of the pituitary and the pineal glands are modified nervous tissues, and these glands may retain some of their original nervous connections

3 What effects are produced by artificial stimulation of the nerves that go to the endocrine glands? Direct stimulation of the peripheral end of the splanchnic nerves augments the output of epinephrin, and ultimately exhausts the suprarenal medulla of epinephrin The question of reflex and central control of this suprarenal nervous mechanism is unsettled Competent investigators have reported absolutely contradictory results, and clinical opinions bearing on the question are mere guessing This is the only securely established instance of nervous control of a possible endocrine gland, but the output controlled by the suprarenal nerves has yet to prove its right to be classed as a hormone

The methods used in the attempts to demonstrate nervous control of the hypophysis have been shown to be unreliable We have a mass of data, most of it contradictory, and the remainder not yet confirmed, on the nervous control of the thyroid activity We may disregard the histologic reports and the alleged surgical cure of toxic goiter by section of the thyroid nerves (the cervical sympathetic) The change of iodin content of the gland on stimulation of the thyroid nerves is questioned, and even if such change should be conclusively established, the interpretation of the fact is uncertain But there are two lines of experimental evidence that require serious attention It seems to be a fact that stimulation of the thyroid nerves induces changes in the electrical potential in the gland (usually increased negativity but sometimes positivity) Similar experiments (pituitary injections) on the mammary glands have been reported as proving that pituitary extract causes secretion of milk The electrical change following administration of pituitary extract is due to contraction of the smooth musculature of the mammary glands Before the electrical variations in the thyroid gland on stimulation of the thyroid nerves can be accepted as proving the nervous control of thyroid activity, it must be shown that the electrical change is not induced by the contraction (or relaxation) of the arteries, capillaries and veins in the gland It is further reported that stimulation of thyroid nerves and mechanical massage of the thyroid gland in cats under light ether anesthesia accelerates the denervated heart Massage of the thyroids for two minutes is reported to accelerate the heart for from thirty to ninety minutes after a latent period of from fifteen to twenty minutes The investigators state that the experiment does not succeed in the months of March and April The experiment, when successful, is interpreted as showing that mechanical massage and nerve stimulation increase the output of the thyroid hormone, which in turn accelerates the heart indirectly by increasing the body metabolism It is pointed out as supporting evidence that mechanical massage of the suprarenals increases the output of epinephrin We may note as equally true that mechanical massage of the kidneys the pancreas, and the salivary and gastric glands does not stimulate these glands to increased activity The failure of the experiment in March and April is puzzling, as no one has shown any seasonal variations in the thyroid hormone of the cat If the cat's thyroids are shy of iodin in March and April, such deficiency can easily be remedied by feeding iodids But the most serious difficulty in accepting the positive findings as evidence of nervous control of thyroid activity is the prompt appearance and rapid cessation of the cardiac acceleration, the whole reaction being over within one to two hours, while it appears that a single intravenous injection of large or small doses of Kendall's thyroxin (a product assumed to be pure thyroid hormone) is reported to have no effect on the metabolism during the first twelve to twenty-four hours then the increase in basal metabolic rate begins, reaches its maximum increase in from three to seven days, and slowly subsides to normal in from three to six weeks This, if true, is surely a different reaction from that described as following the massage of the thyroid or stimulation of the thyroid nerves

The question of endocrine hypofunction and hyperfunction through direct nervous control is of great practical and theoretical importance But despite the great amount of painstaking work in this field (and disregarding the still greater amount of speculation), it must be recognized that the entire question is an open one, except for the suprarenal medulla Let us hope that the future will record better controlled observations and less speculation But it seems to me that this statement is permissible Endocrine secretory nerves, if present, play a minor or negligible role in the normal and pathologic activity of the glands, otherwise demonstrable disturbances should be produced by denervation of the glands It should, of course, be recognized that extreme changes in nervous activity may induce endocrine hypofunction or hyperfunction indirectly or by way of the blood through changes in metabolism

ENDOCRINE HYPOFUNCTION AND HYPERFUNCTION THROUGH MUTUAL STIMULATION OR INHIBITION OF DIFFERENT ENDOCRINE GLANDS

In this field appears the maximum of fiction and the minimum of established facts The principal facts are these

1 It appears that the ovaries and testes (at least in mammals) cannot develop or maintain their normal function in marked hypothyroidism or marked hypopituitarism

Dr. Robert Fleig Library
U. S. U. Medical College
29570

2 Thyroidectomy and, in some species at least, gonadectomy induces some hyperplasia of the hypophysis

3 Thyroid feeding in experimental animals over long periods appears to induce some hyperplasia of the suprarenals (and the hypophysis), but this has probably no direct endocrine significance, because the thyroid feeding causes at the same time hyperplasia of the heart, the liver, the spleen and the kidneys

4 Hypertrophy of the parathyroids has been described in thyroidectomized tadpoles

5 In some cases, tumors of the suprarenal cortex seem to hasten maturation of the gonads, and gonadectomy may be followed by hyperplasia of the suprarenal cortex

6 Castration retards the involution of the thymus This may mean that hormones from a mature gonad are directly or indirectly responsible for the postadolescence involution of the thymus It has no further endocrine significance, since evidence is lacking for any endocrine activity of the thymus itself

7 It is reported that crushing the suprarenal cortex induces a temporary fever, and that the latter is aborted by thyroidectomy Assuming this to be a fact, it might indicate a stimulating action of the suprarenal cortex on the thyroid, inasmuch as complete suprarenalectomy does not induce hyperpyrexia But crushing the suprarenals is not a simple experiment, and we must await further work before the results can be clearly interpreted in the sense of mutual endocrine control It may be noted in this connection that the feeding of suprarenal, that is, cortical residue or extract, is reported as a cure of toxic goiter If toxic goiter means thyroid hyperactivity, this may indicate inhibitory action of the suprarenal cortex on the thyroid But all of us know that the "cures" for mild cases of toxic goiter are legion, and severe cases may resist all available therapy, including rest and diet

If the foregoing facts are restated in terms of endocrine interdependence, the situation is this The failure of gonad function in hyperthyroidism is probably due to the profound distribution of metabolism In cretinism and myxedema, there is evidence of degeneration or atrophic changes in most of the organs of the body It is well known that depression of the gonads is a frequent effect of metabolic disturbances from faulty diets, as well as from chronic maladies resulting in cachexia The failure of gonad function in frank hypopituitarism may also be due to the general impairment of growth and metabolism, but this is less certain, because the disturbance of metabolism in hypopituitarism appears to be less profound than in hypothyroidism *But we are not justified in interpreting* the fact in the sense of a direct stimulation of the gonads by pituitary hormones, since pituitary feeding seems to have no influence on gonad development, and acromegaly itself may be accompanied by gonad depression rather than the reverse The possible significance of the hyperplasia in some ductless glands following hypo-activity or hyperactivity in another gland system will be considered in a later section At present, there is no evidence that hypo-activity or hyperactivity of any endocrine system, outside of the specific gland involved, can produce or prevent diabetes, myxedema, Addison's disease, infantilism or acromegaly Despite this fact, the thyroid-pituitary-pancreas-suprarenal-gonad group will probably continue to be a favorite exercise ground for speculative physiology and therapy in regard to mutual hormone control

THE QUESTION OF HYPERFUNCTION IN CASES OF GLANDULAR HYPERPLASIAS

There is a tendency among both laboratory workers and clinicians to interpret glandular hyperplasias, that is, increase in gland volume by increase in the number of apparently normal cells, as evidence of glandular hyperfunction This interpretation is also applied to adenomatous hyperplasias, especially of the thyroid, the pituitary gland and the suprarenal cortex We must recognize that on the anatomic and histologic basis alone this interpretation is a theory that may be 100 per cent correct or 100 per cent wrong We have some reliable histologic criteria of the state of secretory rest and secretory exhaustion in the case of the digestive glands, and previous degrees of activity of the digestive glands can be inferred by the degree of depletion of so-called secretion granules, but it must be recognized that this correlation of histologic changes with the state of activity would have been purely theoretical even for the digestive glands, except for the fact that we have a direct measure of the activity of the digestive glands in the output of the digestive juices As previously stated, we have no certain means of directly measuring the rate of output or concentration of the hormones in the blood, except epinephrin, and this is not an important hormone, if it belongs in that group at all Hence, we are limited to attempts to correlate gland histology with body symptoms that may or may not be specific effects of hyperactivity or hypo-activity of the gland in question We have microchemical tests for iron, glycogen, fat, etc, in the cells, but none for the hormones

It appears that thyroid colloids can be stained inside the thyroid cells, but we do not know the relation of thyroid colloid in the cells or in the lumen of the gland to the rate of output of thyroid hormone Diagnosis of toxic goiter from the structure of the thyroid or the thyroid adenoma alone is, at present, merely guesswork

In the same way, variations in kinds and numbers of cells or granules in the cells in tumors and hyperplasias of the hypophysis, particularly if the studies are made on ordinary postmortem material, permit no conclusion as to hyperfunction And the situation is scarcely better in regard to the relation of the pancreas to clinical diabetes Postmortem examination reveals a high percentage of pancreatic lesions in persons having no diabetes The hydropic degeneration of island cells usually found in the pancreas of diabetic patients is regarded by some as one of the *effects* of the diabetes It is generally agreed that many cases of fatal diabetes could not have been diagnosed by the histology of the pancreas alone It is probable that increase or decrease in some cell functions antedates structural changes in the cells as revealed by present methods

In recent years, much attention has been given to the endocrine glands as related to various types of nervous disorders The difficulties in this field are increased by the fact that we have as yet no reliable method of studying functional nervous disorders in animals under experimental interference with the ductless glands By the law of chance, some endocrine disturbance will be present in a certain percentage of insane persons, even if there is no causal relationship between the two phenomena The literature records a high percentage of what appears, microscopically to be pathologic endocrine changes in necropsies of such patients The significance of such pathologic

endocrine changes (mostly hypoplasia or atrophy), in the cause and course of the nervous disease, is most uncertain, especially when physical or physiologic signs of specific endocrine dysfunction are lacking Such endocrine changes may have no more significance than the high percentage of destruction in the pancreas in persons past middle life, dying from diseases other than diabetes

We have examples of endocrine therapy in nervous disorders that display the courage of ignorance I do not know what you think of suprarenalectomy as a cure for idiopathic epilepsy, but for the present I would leave the suprarenals alone and operate on the patient's pocketbook by some other route

Has, then, the microscope ceased to be a useful tool in biologic investigation? On the contrary, let the tribe of microbiologists increase But I plead for greater discernment in the physiologic interpretations of microscopic findings

THE EVIDENCE FOR ENDOCRINE HYPOFUNCTION AND HYPERFUNCTION FROM THE FIELD OF ORGANOTHERAPY

Except for the condition of hypothyroidism, the extensive literature on clinical and experimental organotherapy has so far yielded little or nothing conclusive touching endocrine dysfunctions This should cause no surprise Organotherapy can have no effect in maladies due to dysfunction of ductless glands that function on the principle of detoxication And in the case of glands that function by producing hormones, organotherapy may fail now and forever, (1) if the hormones are not stored up in the gland, (2) if they are too unstable for the necessary chemical processes of isolation for intravenous or hypodermic administration, or (3) if, on oral administration, they are destroyed in the processes of digestion and absorption

With the exception of the thyroid hormone, and the drugs epinephrin and pituitary extracts, we literally do not know what we are feeding when hypophysis suprarenal, testes, ovaries, pancreas or parathyroid preparations are administered to patients Moreover, the specific endocrine factor in the malady in which organotherapy is tried is often a matter of conjecture That is to say, we are administering "unknowns" to cure diseases of unknown origin

Organotherapy has been tried in literally every disease known to man Except for the thyroid, the results are so conflicting that they seem to depend not on drugs, but on the physician who prescribes them Fifteen years ago, Pohl's spermin or testicle extract was a cure-all in Russia, today, pluriglandular proprietaries are doing even greater wonders in our country, according to the testimonials Let us keep a few things clearly in mind in this connection

1 So far, it has not been possible by organotherapy to appreciably influence the impaired functions due to gonadectomy, ovariectomy, parathyroidectomy, pancreatectomy[1] or hypophysectomy in animals In these cases, we know at least the initial pathology, even if we do not know what we are feeding in the gland extracts

2 The history of medicine and of quackery teaches honest men to be slow in ascribing specific values to any therapeutic measure that seems to improve subjective symptoms, or to cure in the field of the functional nervous diseases

3 The trial-and-error method, or empiric organotherapy, is a legitimate path to follow But I think you will agree with me that it is not a path of progress when the trials are so made that *nothing but error* can result from them The trial frequently consists in improved diet, rest, and gland extracts, the error is the conclusion that the gland extract is responsible for the improvement of the patient Let us not forget that thyroid administration, even in frank hypothyroidism, is in many cases not a complete substitute for the normal thyroid And thyroid therapy is our best, if not our only case

It is scarcely necessary to refer to the ease and assurance with which alleged endocrine disorders are diagnosed and treated with gland extracts by men of good standing in the medical profession Some aspects of the literature on glandular extract therapy today remind one of the age of demonology in medicine Following are four typical citations, not from Alexander Dowie, Louis Berman or Mary Baker Eddy, but from our respectable medical journals

> Clinical studies have proved that certain physiologic and structural markings are constant to certain glandular types and by physical objective examination alone without other information we can make an accurate diagnosis
>
> The alert aggressive attitude of the healthy young man and the similar though feminized, pose of the healthy young woman are in large part an evidence of thyroid activity The tremors and blushes *the sentiment of the young woman* the nervous apprehension of the young man under emotional stimulation are also largely evidences of thyroid activity The blushing of the sensitive young girl or boy is but a neurocirculatory reflex exaggerated by thyroid overactivity into the neurocirculatory instability of the definitely hyperthyroid patient
>
> Periods of great emotional output such as courtship, early months of marriage and the more active phases of an artist's career are accompanied by enlargement of the thyroid
>
> There is also something closely allied to a diminished action of the thyroid gland that renders the old maid less generous and less spiritually beautiful than the pregnant woman

EVIDENCE OF ENDOCRINE HYPOFUNCTION AND HYPERFUNCTION FROM THE FIELD OF ROENTGEN-RAY THERAPY

The destructive action of the radium and the roentgen rays on tissues is well established, and it is well known that atrophy and hypofunction of such organs as the thyroid, the ovaries and the testes can be induced by these agencies On the theory that doses of roentgen rays too slight to destroy, will stimulate and thus increase the normal functions of glands, the pancreas has been roentgen rayed in diabetes, the hypophysis in Frohlich's syndrome, etc Positive results have been reported, despite the fact that careful experiments on glands, where the activity can be measured with quantitative and qualitative accuracy, have shown only destructive actions by the roentgen ray An almost miraculous result is reported in the case of a 15 year old boy with some Frohlich's syndrome signs "After four roentgen-ray irradiations of the hypophysial region, the penis grew 8 5 cm in three months" Evidently we are witnessing the beginning of a race between roentgenologists and surgeons as harbingers of virilism

The possible stimulating action of radiant energy on the ductless glands should be tried but tried under conditions that permit the evaluation of the results At present, we do not possess any certain means of

1 Work in progress at the University of Toronto seems to promise more positive results from the pancreas hormone in experimental diabetes

stimulating any ductless gland, "gently" or otherwise, except possibly through the food, and this is probably not specific. Those who speak with such ease and assurance of "stimulating" this, that or the other endocrine gland are merely giving a demonstration of their ignorance.

THE ETIOLOGY OF ENDOCRINE APLASIA AND HYPERPLASIA IN MAN

Destructive lesions of the endocrine glands, such as tumors, tuberculosis, cystic degeneration and fibrosis, are not peculiar to these organs, and consideration of the etiology of these lesions would take us too far afield.

Factors that may be primary in other aplasias and hyperplasias are *heredity, undernutrition, intoxication* from deranged metabolism (qualitative and quantitative) and infections (specific and general).

The possible hereditary factors have not yet been seriously investigated.

Some of the ductless glands appear to be readily disturbed by undernutrition, or unbalanced diets. It is fairly certain that some iodin in the food is necessary for the normal activity of the thyroids. There is considerable literature pointing toward infection as the primary factor in certain types of thyroid hyperplasia. But the question is still open. It is possible that endocrine aplasias and hyperplasias are induced by a variety of factors. Research in this important and difficult field is being neglected in comparison with the amount of attention devoted to the less difficult and more spectacular (and remunerative) administration of gland products.

CONCLUSION

No single phase of endocrine dysfunction is satisfactorily worked out today, either clinically or experimentally. I have endeavored to present the established facts and what appear to be obstacles to progress in baseless speculations and uncritical practice. I am not foolish enough to believe that the former is free from flaws, and some of you may feel that my strictures on the latter are too severe, especially coming from an experimental physiologist. But I have not spoken as a pharisee or as a mere arm-chair iconoclast. The credit for progress made and the blame for errors committed are shared by the clinical and laboratory groups. I leave out of consideration the hopelessly ignorant and the actually dishonest who, no matter what their position and training, belong to the genus *quack*. One sure way of inviting defeat is to underestimate the resourcefulness of the enemy. Failure to recognize the complexity of every endocrine problem is an equally serious obstacle to victory. In following the hormone theory alone, we may, in the case of some of the ductless glands, even be way off the main road.

I believe that much of the glandular therapy of today, however harmless to the patient, injures the good name of the medical profession with intelligent laymen. We cannot practice quack methods and escape the just censure of society.

The quack diagnoses every ailment with ease, and offers remedies for every disease with assurance. The good physician knows that he is neither omniscient nor omnipotent in the field of disease, and the educated layman knows this as well as the physician. Then, why pretend? Bluff may succeed for a time, but honesty is better for society, and what is best for society is best for the medical profession. It is related, in the most ancient medical record now known, the Smith Papyrus, that the good physician in Egypt 5,000 years ago practiced medicine with the same honesty and the same quality of intelligence as that of the good physician of today. When physicians of that age knew, or thought they knew, that no available remedy would help the patient, they did nothing, while the quack worked his "cures" with the hookums of that age.

SOME PRINCIPLES OF ENDOCRINOLOGY APPLICABLE TO ORGANOTHERAPY*

R. G. HOSKINS, PHD., M.D.
Professor of Physiology, Ohio State University College of Medicine
COLUMBUS, OHIO

In a field of biology the bibliography of which runs to 500 pages, the need for the formulation of principles might be expected long since to have passed.[1] To any one conversant, however, with the endocrine literature, it is obvious that no general agreement on principles—and hence on practice—has yet been reached.

Endocrinology is to an unusual degree an empiric field. Our fundamental conceptions have been attained largely by clinical observations of end-results rather than by rational induction from basic facts determined, after the approved fashion, by controlled experimentation. Empiricism has deserved much of the odium that it carries. That it has a legitimate place in medicine, however, is tacitly conceded by every one who prescribes any medicament the pharmacology of which is not fully known. Indeed, it has often been said that the value of any procedure in medicine must finally be determined empirically in the crucible of the clinic. The figure is apt, but let us recognize that a crucible is not an open hearth into which junk may promiscuously be thrown, nor is the result of a crucible test determined by the amount of smoke and spluttering produced. The only empiricism that is of value is that which results in well substantiated facts. When these facts can be adequately systematized they become science, but as facts, they are no more true than they were before.

Much of the existing confusion in the endocrine field would appear to be due to overanxiety to escape the reproach of empiricism—to force rationalization when no genuine rationalization is possible. In such attempts, one class of writers habitually misuses the form of inductive logic, selecting from the vast accumulation of data such as appeal to them, and ignoring such as are inconvenient. Thus, their basic "principles" are derived. Any writer adopting this method has no grounds for complaint that his dishonesty in dealing with the data of others leads to the conviction that he is equally dishonest in dealing with his own. The device of attempting to escape the necessity of patience and thoroughness by dubious theorizing should be discarded. It has brought contempt upon much that passes as endocrine literature.

ENDOCRINE ORGANS AND THEIR FUNCTIONS

So far are we from accepted principles that it is not amiss, even at this late day, to inquire, What is an

* Read before the joint meeting of the Section on Practice of Medicine, the Section on Pharmacology and Therapeutics and the Section on Pathology and Physiology at the Seventy-Third Annual Session of the American Medical Association, St. Louis, May, 1922.

1. The bibliography of the fourth edition of Biedl's Innere Sekretion comprises 474 pages and many articles have appeared since the published list was completed.

endocrine organ? Gley has formulated three determining conditions The gland must show the histologic picture and the cytologic polarity of a secreting structure This principle at once excludes from the endocrine congeries the thymus gland and the neural lobe of the hypophysis, but these in many circles are still in good and regular standing A second principle is that from the organ in question an active substance must be obtained Such a substance may be, but probably is not, a hormone Final logical proof demands that the peculiar principle be detected in the effluent blood or lymph In case of nearly all the assumed endocrine structures, this last step remains yet to be taken

It is widely assumed that perturbed function in any one gland is characteristically followed by changes in others It is presumed that any endocrine gland may show a condition of normality, hyperfunction, hypofunction, dysfunction, dysfunction plus hypofunction, or dysfunction plus hyperfunction, that is, one normal and five abnormal states Theoretically there exist, therefore, five uniglandular syndromes for each endocrine organ The more enthusiastic endocrinologists assert the existence of at least nine endocrine organs, each of which presumably can assume any one of the six states The possible number of basic combinations, then, is six to the ninth power, or 10,077,696 One of these combinations is normality of all glands, hence the theoretical number of endocrinopathies is 10,077,695 If one is more modest and assumes the existence of only six glands, there are but a paltry 46,655 possible endocrinopathies [2] To what extent these may be modified by relationships of vicarious function, interstimulation and interinhibition of varying degrees, one cannot offer even an intelligent guess In any case, however, few of the theoretically possible endocrinopathies have ever been recognized clinically, and of these, still fewer have been reproduced experimentally When each factor in each syndrome can be recognized and appraised, clinical endocrinology will have become a science By that time even medicine as a whole may conceivably have become a science

SOURCE AND VALUE OF GLANDULAR PRODUCTS

Perhaps the most interesting immediate question to the practical endocrine therapist is, From what glands can active hormone products be derived? Judged by the "therapeutic test" in the hands of credulous impressionists, the number is extensive The number for which there is adequate proof is much smaller The proverbial "crucible" is still spluttering The most convincing evidence on this point is being obtained by investigators on tadpoles Seemingly, a healthy tadpole is vastly different from a sick woman Practically, the tadpole is a very delicate physicochemical indicator of the operation of factors that modify vital processes, and the determination of such factors is the primary problem of the endocrinologist

As to the clinical value of glandular products now available, much uncertainty exists There is great need of standardization of methods of manufacture and of assaying Even granted an endocrine function for a given gland, the quantity of hormone present at any one time may be very minute Moreover, even if it exists in relatively large quantities in the fresh gland, there is no certainty that it will not all be lost in the manufacture of gland products Furthermore, we know little as to the extent to which hormones are absorbed or destroyed in the alimentary tract It would seem wise for the present for the individual observer in practical work to adopt some one preparation of each gland and use that exclusively for considerable periods This would help to eliminate one of the variables that render the therapeutic literature so difficult to evaluate It would also be desirable, until the actual value of each product is determined, to use fresh gland substance, but this is usually impracticable It would be practicable, however, to obtain, in many cases, desiccated material that has not been subjected to any process of extraction or chemical treatment From the standpoint of the pharmaceutical manufacturer, such a suggestion is not attractive, but a large body of evidence regarding the efficacy of the unaltered gland substance is needed as a basis from which to determine the relative value of special products The ideal state will, of course, be reached when each active principle has been isolated and synthesized If organotherapy ever takes the place that *its more enthusiastic* proponents prophesy, the available supply of natural products will be vastly inadequate It is said, for instance, to require 5,000 calves to produce a pound of desiccated pineal substance

REACTIONS

Another question of major importance has scarcely as yet been even considered, namely, What conditions modify the reactions to any given hormone? In case of epinephrin, it has been shown that the vasomotor reactions are diametrically opposite, depending on initial blood pressure, bodily vitality and temperature, dosage, reaction of the menstruum, and depth of anesthesia In case of the thyroid there is evidence that change of dosage may reverse the reaction from anabolic to catabolic Pituitary extract causes or checks diuresis, depending on attendant conditions It is not unlikely that similar reversals of reaction will be found in the case of other gland products

In the case of products that influence growth, the normal occurrence of proliferative cycles is of considerable importance A given hormone might materially influence developmental processes at one time and be quite without influence at another

A principle worthy of particular stress is that a given endocrinopathy may be readily amenable to treatment in its earlier stages, but quite intractable, later Skeletal growth, for example, can no longer be influenced after closure of the epiphyseal junctures Early diagnosis and early treatment are therefore of the utmost importance

OBJECT OF ORGANOTHERAPY

Endocrine products may be prescribed with several purposes in view The most definite is merely to compensate additively for a deficient hormone Thyroid gland is thus administered for myxedema The possibilities of even this type of therapy, however, remain yet largely to be determined Hallion has suggested that gland products often act by stimulating the homologous gland This statement has been accepted by some writers as a biologic law There is some definite evidence in its support, but the extent of its applicability remains for future determination As to the usefulness of gland products to inhibit antagonistic glands, we have little significant information Desiccated pancreas is said to depress the activity of the suprarenal glands, but what is apparently meant is that it is a slowly acting vasodepressant If it be such,

2 I am indebted to my colleague Prof W M Barrows for this mathematical formulation of the situation

the substance may be of practical value, but there is little rational basis for regarding it as a suprarenal antagonist

The use of endocrine products for their purely nonspecific pharmacologic properties offers a promising field for further investigation The use of epinephrin and pituitary extract has been especially stressed As regards pituitary extract, the prevailing opinion of recent years has tended toward conservatism There are even extremists who would banish it from the field of obstetrics on the ground that the reactivity of patients varies so widely as to render it always potentially dangerous The sublingual administration of the drug, however, would seem largely to eliminate danger and to widen materially the indications for its use in any condition wherein a general smooth muscle stimulant is indicated Another promising field for therapeutic investigation is the utility of thyroid as a nonspecific drug The thyroid hormone appears to be a general cell stimulant, and hence to be widely indicated in conditions in which depressed functional activity is a predominant feature

DOSAGE

One of the most troublesome problems in organotherapy is that of dosage In addition to variability of products, the variability of patients is striking In current practice a given substance may be administered in quantities varying from a fraction of a grain to a hundred grains In case of the thyroid, basal metabolism affords a control It has been suggested that the dosage of desiccated hypophysis can be determined by the administration of increasing amounts to the point of producing headache, and then dropping to about half of this dosage Empirically, it seems to be fairly clear that alternate periods of administration and of rest give best results

At present there is much difference of opinion as to whether endocrine products should be prescribed singly or in combination Looking to the interest of humanity at large, present and future, single products should be employed whenever there is a reasonable chance of their proving helpful In this way only can we hope within any reasonable time to determine the independent value of each product Whatever be the intricacy of organ involvement in the various endocrinopathies, it is to be supposed that ordinarily some one gland is primarily at fault Biedl has stressed the fact that, with correct diagnosis on this point, uniglandular therapy may give brilliant results

On *a priori* grounds, however, if endocrine syndromes are, as many maintain, always, or even commonly, pluriglandular, more rapid amelioration might be expected if a suitable pluriglandular formula were used Practically, rational pluriglandular therapy would seem to demand a large number of different combinations, and these in differing proportions in each case, as indicated by the degree of involvement of each gland and the susceptibility of the patient

It has been suggested that the free use of pluriglandular formulas is desirable on the supposition that the body cells will select those hormones needed and discard the rest This theory apparently embodies a half truth That the various body cells do select from the blood stream the substances necessary for their metabolism is obvious the sphenoid bone and the vermiform appendix are fashioned from the same pabulum That the body cells are able to reject any hormone, however, I know of no evidence, whereas, it is known that hormones are often assimulated by body cells to their own detriment or even death In any unanalyzed syndrome, it would seem that a random hormone would be potentially harmful to the same extent that it would be potentially helpful

CONCLUSION

It seems desirable again to emphasize the complicated nature of the problems with which the endocrine therapeutist is confronted Little is to be expected from nonchalant attempts to solve these problems by superficial observations Nor can a thoughtful clinician take seriously the claim that overenthusiastic use of gland products is to the best interest of the patient The arguments adduced are precisely the stock arguments of the cultists and nostrum venders Ultimately, practical organotherapy will have to be reduced to a statistical basis This will require the accumulation of a much greater fund of well established observations, both positive and negative There is need for many more careful studies of individual cases as well as extensive series of cases Almost any endocrine case presents a research problem worthy of exacting study

Individual endeavor by volunteer investigators is making some headway, but progress is necessarily slow There is need for the founding of one or more well equipped and well financed institutions devoted specifically and in a large way to endocrine research Such an institution should include a hospital with personnel and equipment for bringing to bear the best modern diagnostic and therapeutic technic and especially for careful metabolic studies In association with this hospital there should be provided adequate facilities for coordinated animal experimentation

Endocrinology in some form is going to flourish indefinitely Parlor endocrinology is even displacing parlor Freudism For better or for worse, endocrinology has acquired a recognized place in the field of medicine For two decades practitioners have been avidly seeking enlightenment regarding the practical, everyday problems with which they are confronted As to how their needs have been met, let the present state of organotherapy testify The problems offered are such as to tax the best efforts of the best trained therapeutists Shall these gather their robes about them and pass by on the other side? To the extent that enlightened, critical leadership fails, to that extent will cheap, commercialized endocrinology have a large following, and medicine be cheapened to the same degree

ABSTRACT OF DISCUSSION

ON PAPERS OF DRS BARKER CANNON AUB, CARLSON AND HOSKINS

DR WILLIAM ENGELBACH, St Louis As a whole, the symposium impresses one with the hypercriticism of those men who are seriously taking up the study of internal secretions It gives a good general perspective of the relative importance of the internal secretions The disorders of the ductless glands are only a small part of internal medicine, but this small, yet important, field has been greatly neglected The most dangerous thing that confronts clinicians is the early misinterpretation of pathologic endocrine signs present in many normal persons We each belong to a certain endocrine type, and we have to go farther than the establishing of a type picture to make a diagnosis of a ductless gland disorder For instance, if a person has headache and he happens to be of the acromegalic type it does not follow that the headache is of hypophysial origin There has to be more evidence of pituitary disorder before that relation can be proved The relation of the sympathetic nervous system to the ductless glands and the body as a whole must be given

more consideration As pointed out by Dr Cannon, the clinical experiments on vagotomy have been of value in excluding the positive basis on which this complex was introduced I regret that Dr Aub did not say more about those peculiar adiposities related to pituitary disease with a low basal metabolic rate The most recent literature credits the pituitary gland with diminishing metabolism As that metabolic rate is taken today, based on the oxygen exchange in the lungs, comparatively all these patients having pituitary adiposity experience no change in their basal metabolic rate, yet they gain weight rapidly It will be necessary to have other tests—fat metabolism must be investigated, with other estimations of metabolism before this is explained The cooperation of the best men in their various experimental departments will promote a better understanding of this complex subject Dr Hoskins' paper is timely in that it draws attention to the varied terminology and nomenclature prevalent at this time Terms such as dystrophy and dyspituitarism, used as a cloak for ignorance should be abandoned The physiologists have not proved that we have a specific substance from some of these glands There is no question that there is overenthusiasm in the treatment of ductless gland disorders Undoubtedly, we can accomplish more by uniglandular treatment, even if we have a pluriglandular disorder Make the test with one gland substance for a long time to determine whether you get a therapeutic reaction, and then, if you think there is another gland involved, give the other substance singly, noting results Stock prescriptions of pluriglandular substances are difficult to control or estimate For instance, a preparation containing one-half grain of thyroid, combined with epinephrin and spermin given to a person who needs 5 grains of thyroid substance would be insufficient to meet indications We have to know how to give each glandular substance up to the physiologic effect and this varies in each individual patient

DR LEONARD G ROWNTREE, Rochester Minn Endocrinology is still young It is far from a science Facts are being pried from nature, and these facts are being scrutinized, systematized and correlated Science will eventually evolve The need in endocrinology today is, as it always has been, well planned and carefully executed clinical and experimental investigations, accompanied by analytic and critical judgment Dr Cannon has dealt largely with matters pertaining to the control of the activity of the endocrine glands, considerations which led Bayliss and Starling years ago to the discovery of hormones To this field, Dr Cannon himself has contributed much He demands facts and not speculation, and it was extremely interesting to hear him say that he hints at correlation of function, but needs more evidence before accepting these correlations Dr Aub reports the results of studies where, happily, objective control is possible He has furnished a model in the differentiation of facts from hypotheses and theories and he has made contributions to our knowledge of the factors involved in the control of metabolism and the mechanism involved in this control Dr Carlson has directed a searching inquiry into many of our physiologic and clinical beliefs, and has emphasized particularly the shortcomings of clinicians and also of physiologists As a physiologist, he has subjected to critical judgment our claims concerning the qualitative and quantitative changes resulting from manipulative procedures or from processes of disease He has attempted correlations of clinical, physiologic and pathologic data which, in part, have puzzled and baffled clinicians and which apparently are also somewhat puzzling and baffling to him Dr Hoskins has emphasized the magnitude of the therapeutic problem and has called on the leaders of the profession to exercise leadership in therapy as well as in diagnosis There are certain needs in endocrinology (1) postulates in endocrinology analogous to Koch's postulates in bacteriology, (2) a common basis among workers in the same field, and between workers in the various fields concerned in endocrinology from the standpoint first, of a common point of view, and, second, of nomenclature (Does hyperplasia for instance, mean the same thing to all workers in all fields? Does it mean the same to all pathologists?), (3) clinical classifications and (4) objective control of therapy, such as we have in basal metabolism, urine output under the action of posterior lobe of the pituitary and blood pressure in Addison's disease Progress in endocrinology will come slowly through thoroughly correlated, adequately controlled investigations, in which the findings are subjected to interpretation based on analytic and critical judgment

DR WALTER M BOOTHBY, Rochester, Minn In a myxedematous patient, 10 mg of thyroxin, injected intravenously, elevates the basal metabolic rate on the average 28 points The height of the curve comes from the fifth to the tenth day after injection, it remains at this level for several days, and then gradually declines, reaching the original level from fifty to sixty days later In the clinical administration of thyroxin or thyroid extract this delayed and long continued action of thyroxin must be taken into account in the determination of the size of the dose also the fact that any change in the dose will not produce its main effect for five or ten days Failure to appreciate this delayed effect has made it difficult to regulate properly the amount of thyroid extract required, and has led to the custom of intermittent administration It is better however to establish a correct dose that can be given indefinitely, and it has been found that 1 6 mg of thyroxin is usually the correct daily dose The curve of the calorigenic effect of epinephrin is similar in form to that of thyroxin, provided that the time element is changed to minutes in the former case from that of days for thyroxin In confirmation of Dr Aub's work, we have been able to show in dogs that it is possible to obtain a calorigenic effect from such doses of epinephrin as Cannon and Stewart and Rogoff have shown to be within the powers of the suprarenal glands to secrete

DR H T HYMAN, New York I was glad that Dr Cannon called attention to the work that renders untenable the tonicity theory of the regulation of the involuntary nervous system Dr Cannon presented again his emergency theory and the evidence favoring it, but did not refer to the work at Western Reserve University which refutes many of the experiments on which the theory rests With reference to the nervous influences on the thyroid, two facts are contrary to the evidence on which the supposition rests 1 Thyroxin effects do not occur for hours, even days, after injection, while the supposed increased output of thyroxin following nerve stimulation is manifested in a few moments in the experiments quoted 2 The supposed effect of the increased thyroxin output in the experiments of Levy we have produced weeks after thyroidectomy and have shown to be due to changes in the involuntary nervous system We are indebted to Drs Carlson and Hoskins for their interpretation of clinical results We know that it is necessary to ablate about 90 per cent of a gland in order to produce evidences of insufficiency in the laboratory, that even with a fragment of active glandular tissue remaining, normal function is maintained Under these circumstances, where is the evidence for the much discussed formes frustes? So far as we know, no gland can function for another Where, then, are the evidences for vicarious functioning? How can endocrinologists refer to results following endocrine therapy as "specific results when we have no means of assaying glandular preparations and when we know nothing of the absorption? We speak of hyperfunction When we are unaware of the output into the veins of the glands under normal conditions, how can we postulate a hyperfunction? Most of the symptoms attributed to disturbance of the ductless glands can be produced only through the involuntary nervous system Consequently no more important step in our knowledge must be sought than the mechanism by which the ductless glands affect the involuntary nervous system

DR WALTER TIMME, New York Dr Hoskins' mathematics are very simple algebra—on the basis of permutations and computations As a matter of fact that principle of mathematics depends on constant quantities The endocrine system has no constant quantities, only variables, and that needs a higher type of mathematics—a calculus which furnishes information about differentials—but the end-result has to be integrated by integral calculus So we are still further along than we were before and at the same time more deeply involved The answer to any integral calculus problem dealing with variables is never one term or absolute quantity It is always represented in a series of terms combined in a formula of functions of the factors involved To illustrate A middle aged woman gives the clinical aspects of myxedema

the substance may be of practical value, but there is little rational basis for regarding it as a suprarenal antagonist

The use of endocrine products for their purely nonspecific pharmacologic properties offers a promising field for further investigation The use of epinephrin and pituitary extract has been especially stressed As regards pituitary extract, the prevailing opinion of recent years has tended toward conservatism There are even extremists who would banish it from the field of obstetrics on the ground that the reactivity of patients varies so widely as to render it always potentially dangerous The sublingual administration of the drug, however, would seem largely to eliminate danger and to widen materially the indications for its use in any condition wherein a general smooth muscle stimulant is indicated Another promising field for therapeutic investigation is the utility of thyroid as a nonspecific drug The thyroid hormone appears to be a general cell stimulant, and hence to be widely indicated in conditions in which depressed functional activity is a predominant feature

DOSAGE

One of the most troublesome problems in organotherapy is that of dosage In addition to variability of products, the variability of patients is striking In current practice a given substance may be administered in quantities varying from a fraction of a grain to a hundred grains In case of the thyroid, basal metabolism affords a control It has been suggested that the dosage of desiccated hypophysis can be determined by the administration of increasing amounts to the point of producing headache, and then dropping to about half of this dosage Empirically, it seems to be fairly clear that alternate periods of administration and of rest give best results

At present there is much difference of opinion as to whether endocrine products should be prescribed singly or in combination Looking to the interest of humanity at large, present and future, single products should be employed whenever there is a reasonable chance of their proving helpful In this way only can we hope within any reasonable time to determine the independent value of each product Whatever be the intricacy of organ involvement in the various endocrinopathies, it is to be supposed that ordinarily some one gland is primarily at fault Biedl has stressed the fact that, with correct diagnosis on this point, uniglandular therapy may give brilliant results

On *a priori* grounds, however, if endocrine syndromes are, as many maintain, always, or even commonly, pluriglandular, more rapid amelioration might be expected if a suitable pluriglandular formula were used Practically, rational pluriglandular therapy would seem to demand a large number of different combinations, and these in differing proportions in each case, as indicated by the degree of involvement of each gland and the susceptibility of the patient

It has been suggested that the free use of pluriglandular formulas is desirable on the supposition that the body cells will select those hormones needed and discard the rest This theory apparently embodies a half truth That the various body cells do select from the blood stream the substances necessary for their metabolism is obvious the sphenoid bone and the vermiform appendix are fashioned from the same pabulum That the body cells are able to reject any hormone, however, I know of no evidence, whereas, it is known that hormones are often assimulated by body cells to their own detriment or even death In any unanalyzed syndrome, it would seem that a random hormone would be potentially harmful to the same extent that it would be potentially helpful

CONCLUSION

It seems desirable again to emphasize the complicated nature of the problems with which the endocrine therapeutist is confronted Little is to be expected from nonchalant attempts to solve these problems by superficial observations Nor can a thoughtful clinician take seriously the claim that overenthusiastic use of gland products is to the best interest of the patient The arguments adduced are precisely the stock arguments of the cultists and nostrum venders Ultimately, practical organotherapy will have to be reduced to a statistical basis This will require the accumulation of a much greater fund of well established observations, both positive and negative There is need for many more careful studies of individual cases as well as extensive series of cases Almost any endocrine case presents a research problem worthy of exacting study

Individual endeavor by volunteer investigators is making some headway, but progress is necessarily slow There is need for the founding of one or more well equipped and well financed institutions devoted specifically and in a large way to endocrine research Such an institution should include a hospital with personnel and equipment for bringing to bear the best modern diagnostic and therapeutic technic, and especially for careful metabolic studies In association with this hospital there should be provided adequate facilities for coordinated animal experimentation

Endocrinology in some form is going to flourish indefinitely Parlor endocrinology is even displacing parlor Freudism For better or for worse, endocrinology has acquired a recognized place in the field of medicine For two decades practitioners have been avidly seeking enlightenment regarding the practical, everyday problems with which they are confronted As to how their needs have been met, let the present state of organotherapy testify The problems offered are such as to tax the best efforts of the best trained therapeutists Shall these gather their robes about them and pass by on the other side? To the extent that enlightened, critical leadership fails, to that extent will cheap, commercialized endocrinology have a large following, and medicine be cheapened to the same degree

So far as we know, no gland can function for another Where, then, are the evidences for vicarious functioning? How can endocrinologists refer to results following endocrine therapy as "specific results" when we have no means of assaying glandular preparations and when we know nothing of the absorption? We speak of hyperfunction When we are unaware of the output into the veins of the glands under normal conditions, how can we postulate a hyperfunction? Most of the symptoms attributed to disturbance of the ductless glands can be produced only through the involuntary nervous system Consequently no more important step in our knowledge must be sought than the mechanism by which the ductless glands affect the involuntary nervous system

DR WALTER TIMME, New York Dr Hoskins' mathematics are very simple algebra—on the basis of permutations and computations As a matter of fact, that principle of mathematics depends on constant quantities The endocrine system has no constant quantities, only variables and that needs a higher type of mathematics—a calculus which furnishes information about differentials—but the end-result has to be integrated by integral calculus So we are still further along than we were before and at the same time more deeply involved The answer to any integral calculus problem dealing with variables is never one term or absolute quantity It is always represented in a series of terms combined in a formula of functions of the factors involved To illustrate A middle aged woman gives the clinical aspects of myxedema

her basal metabolic rate was determined by three investigations made by two investigators, and varied from plus 80 per per cent to plus 100 per cent Hence, the men who saw her refused to believe it was myxedema and refused to give her thyroid Examining the case further, we found that she had intense headache, and roentgenographic examination showed she had an enlarged sella turcica and a bitemporal hemianopsia with a diminution of vision Therefore, it was a case of hypophysial mass, plus myxedema She was given small doses of thyroid Within two or three days she began to improve, her headaches began to diminish in severity, and the basal metabolic rate became lower, on no other treatment than the administration of thyroid! It does not mean that the deficiency of the thyroid produced a high metabolic rate, that the hypophysial mass produced the high metabolic rate, the high rate may be due to pressure of the hypophysial mass on parts of the brain In any event, it means that the integration of the syndrome is a formula, and that is what we have to consider in all the innumerable problems which confront us and the formula is one which involves all the varying activities of the glandular elements

DR A S BLUMGARTEN, New York I can discuss the subject only from its clinical aspect and there are two phases to that one is the importance of endocrine study in clinical medicine, and the other is the question of therapy The study of the patient from an endocrine point of view is a valuable adjunct to the ordinary routine physical examination, especially when it is impossible to recognize a pathologic change by present methods of examination Clinically, endocrine disturbances that are presented for treatment are usually disturbances in growth and development and in physiology In the majority of instances the disturbances in development are not amenable to treatment by organotherapy, although the endocrine basis for the condition is apparent The dried extracts of various ductless glands have a limited value, but it is hoped that we shall be able to get better results when we can better recognize the conditions amenable to treatment and have products which can give definite reliable effects The basis of organotherapy is substitution therapy One must be guarded, however, in drawing conclusions, as frequently spontaneous cures and improvements take place For example In the Froelich syndrome of pituitary disturbance, the improvement in genital development following pituitary therapy is often not the result of therapy at all Many of the genital symptoms are merely a retarded puberty, which gets well spontaneously, even without therapy The dosage is another important point in organotherapy Since we are supplying a deficient substance and we have no way of determining the quantitative deficiency, we have no way of determining the dosage I think we can summarize the present status of organotherapy in reference to dried extracts by stating that thyroid extract is curative in cases of thyroid deficiency, such as myxedema and cretinism Pituitary extracts are valuable in relieving many of the symptoms of pituitary deficiency, largely of a subjective nature, and more valuable in females than in males Objective results with pituitary extracts are rather rare The other dried extracts are still in the experimental stage Epinephrin and pituitary extract are useful for the production of their specific pharmacologic effects The problem of the future consists in recognizing specific states of glandular deficiency and obtaining preparations that will produce definite results

DR. HARRY A BAKER, Minneapolis There is a gland of which no mention has ever been made, important in the arrangement and, etiologically, a factor in the derangement of this system, i e, the brain Indeed, the brain ought to be included among the endocrines for though, perhaps, through its subsidiary glands it is occupied in other activities, its chief function is the assimilation of matters sensate into sense and understanding By regarding the brain as the head and front, and the sympathetic nervous system as the equilibrator, it then becomes easy to comprehend how disturbances primarily of the head result in functional derangements, faulty equilibration in metabolic disorders, and the reverse, faulty equilibration continued over a long period of time, resulting in minor or even grave functional disturbances, the relationship being almost as close as the cardiorenal to the organic system

DR LOUIS B WILSON, Rochester, Minn In this congeries of clinicians, physiologists, biochemists and mathematicians I, an old time pathologist and morphologist, feel like one of the slow going high wheeled ox carts of my adopted state in a flock of aeroplanes But I wish to say one word of suggestion to the aeronauts Keep close to the ground when you start, remembering that almost all that we know of the actual facts of disease has been learned at the necropsy table Let us not forget that there is, after all, something in morphology which we cannot ignore in our experimental or physiologic or biochemical work on disease One of the essayists doubted somewhat the correlation of the morphologic evidence of increased activity in the thyroid in relation to hyperthyroidism, because there is an occasional instance in which hypertrophy and hyperplasia of the cells of the thyroid are not coincident with what the clinician says as they appear in the patient Clinical evidence you know, is not always absolutely true Neither is experimental evidence always true I do not find absolute agreement in the pathology and in the diagnoses that have been made There is just a suspicion that the patient did not have what the eminent clinician thought she had When one essayist says he doubts the relationship between parenchymal overgrowth and overfunction in the gland, I think back over the seventeen years that I have spent in examining more than 16 000 thyroids—minutely, not in a single section, but going over them piecemeal by the hundreds of sections—and when I look at my photographs, I ask myself, "Have I been mistaken? Is it after all true that there is not any difference between the histologic evidence, and the facts as shown by the clinician or as thought to be present by the clinician?" We must keep our feet on the ground

DR W B CANNON, Boston I understood Dr Carlson to express himself as not being committed to morphologic change as indicative of disturbed physiologic function And yet when he came to consider the relation of nerves and nerve supply to the glands of internal secretion he used, as part of his evidence regarding these nerves of minor importance the fact that after severance of the nerve little morphologic change in the gland is demonstrable It seems to me that we should not expect more morphologic changes under these circumstances If the glands of internal secretion to which the nerves go are also subject to humoral control, I would agree with him that so far as morphologic evidence is concerned it is of minor importance as bearing on the question of nervous control of the endocrine glands Both he and Dr Hyman were inclined to throw doubt on the evidence we had obtained that the thyroid is subject to nervous control, when we used the denervated heart as an evidence of activity And the reason we threw doubt on that is that following the administration of thyroxin, no effect is noted for from twelve to sixteen hours whereas in the stimulation of the nerve in the heart, it was determined that the effect began in fifteen minutes and reached its acme in about three quarters of an hour or an hour Why that discrepancy should throw doubt on the experiments I have called attention to is difficult for me to see There is a discrepancy there we see that, but why is the doubt thrown altogether in one direction? Here is a substance which has been removed from the thyroid, which has been put through complicated chemical processes processes which we suppose have not left the substance in the original state We are dealing with what is quite possibly a drug, a substance which, to be sure, is capable of affecting metabolism, but to assume that it is the physiologic substance in thyroid activity goes beyond any reason we are justified in taking It is quite possible that thyroxin has to undergo a chemical change before it is capable of acting at all *In the experiments I described in* which the animal was anesthetized and asphyxia was produced, the effects observed could properly be determined as physiologic in character The discrepancy exists, but the doubt is not to be thrown wholly in one direction Dr Hyman asked why I had not called attention to observations made at the Western Reserve University which are contradictory to observations reported today I hope Dr Hyman did not intend to imply that I was suppressing the truth I have so recently called attention to the defects in the evidence

mouth The interesting question here is whether the chronic inflammatory area of leukoplakia is more likely to become the site of cancer than is any other chronic sore of the mouth, for example, the granuloma at the tooth root, or the ulceration from pressure and irritation of a tobacco quid or a jagged tooth crown This question is especially important in view of accumulating evidence that cancer bears a rather constant relation to inflammation

That cancer is contagious in the ordinary meaning of this word is, I think considered quite doubtful However, of the fact of its inoculability there is no doubt, as is proved by animal experiments, and yet practicing surgeons will be disposed to wonder whether cancer is very readily inoculable in the human, for every one of us must have pricked a finger many times without local inoculation in the course of cancer operations, particularly before the day of rubber gloves, which seems strange in view of the high rate of incidence of cancer at the site of inoculation in animals, for example, by Fichera, Nuzum Slye and others Certainly, in view of the results of animal inoculation, one would not care to consult a dentist who does not sterilize his instruments and hands, if there be such a dentist

The occurrence of cancer in plural instances in the same family, "cancer a deux" of married couples, cancer villages, cancer streets, etc have long been looked on as strongly indicating heredity as a factor in cancer etiology These observations, of course, do not establish the truth of heredity Since the same village, street, or home often means the same habits, environment, occupation, etc, it is just as fair to seek the reason for cancer dissemination in the latter group of factors as in the former ones implying familial or other intimate connections Mice experiments (for example, those of Slye) have given much stronger support to the hypothesis of heredity

The question as to whether cancer is primarily of a local or constitutional nature is interesting to any one considering the matter of cancer prevention L Duncan Bulkley[1] has pointed out that, during the last 100 years, many famous surgeons, among them Abernethy, Sir Astley Cooper and Sir James Paget, have expressed the belief that cancer is a constitutional disease Bulkley presents a chart setting forth laboratory findings and statistical, biochemical and clinical evidence in support of his contention He stresses the importance of blood changes in early and late cancer, and of metabolic changes in the system before and after the development of the local cancerous lesion, and states that dozens of hundreds of patients with cancer have been benefited and cured by other than local measures

Moreover, a recent writer[2] declares that cancer has never been proved to be a local disease at any stage and that it has never been proved not to be a constitutional disease at every stage Now, if it were true that cancer is from the beginning a constitutional disease, then, of course, all of our efforts to lower the incidence of cancer of the mouth, jaws and face by the removal of jagged teeth, the cure of leukoplakia, or the interdiction of the pipe when, for example, the area of irritation appears on the lip, would be to little purpose, but every surgeon, out of his own experience, can recall at least several instances in which cancer has been ablated completely and permanently, for example, by the amputation of a hand or foot or removal of a lip, and such men will look with little favor on this view, even though it is held by so earnest and distinguished a man as Bulkley Even those who refuse to admit that "if a man past middle life does not smoke heavily, nor chew tobacco, cares for his teeth and keeps his mouth clean, he is very much less likely to have cancer than one who does not follow the simple laws of mouth hygiene," will admit, at least, that such a man is less likely to have cancer of the mouth, and this is a matter of the greatest importance Even admitting what is probably not true, that is, that cancer is primarily constitutional, it is, nevertheless, of tremendous importance to prevent its appearance in the mouth, since the history of the results of all forms of treatment of cancer of the buccal cavity constitutes a very dark chapter This pitiable record shows its extreme malignancy, principally, of course, because of the richness of this zone in blood and lymph vessels and glands, and the intimate relation to vital structures

That a lesion which is benign in its histologic nature may develop malignant character is no longer open to serious doubt Paine believes that he has observed all stages and sequences of degeneration, from chronic inflammation of the breast to cancer McCarthy's classification of chronic mastitis into primary, secondary and tertiary stages sets forth such sequence

Clarke[3] believes that cancer results from inflammation when the process is prolonged beyond the regenerative power of the tissues, and Dr C H Mayo has expressed the view that cancerous degeneration at the margin of the gastric ulcer may be due to exhaustion of the marginal cells, as a result of a long ineffectual attempt to cover the denuded area Whatever the explanation, empiric proof is abundant to justify the long recognized principle of cancerous degeneration of benign lesions

Naturally, in the region of the mouth, the dentist is the "master man in the struggle to combat malignancy" It is to him that we must look to give out the warning against danger of the early lesions of tobacco, alcohol, hot drinks, pyorrhea, syphilis, etc

It is well established that cancer of the lip, mouth and tongue practically always attacks men who abuse tobacco, have jagged teeth, and ignore the dentist As to lip cancer, the mere fact that 3,500 in round numbers die annually in this country from carcinoma of the lip, demands that interested attention be given to the matter of smoking This, at the present time, concerns men as a rule, since lip cancer is six times more common in men than in women, lip cancer in women nearly always developing among pipe smokers However, if the emancipation of American women in this respect becomes as complete as it is in Scandinavia, where ladies of perfectly apparent refinement smoke black cigars quite publicly, we may expect a higher rate of incidence of lip carcinoma among women

Bloodgood,[4] speaking of tongue cancer says that there is always a warning sore spot, a white patch, or an area of irritation, and that examination and treatment at once protects from cancer He further declares that the warnings of cancer of the tongue are definite and that in the beginning the lesions are not cancer These warnings are white patches, bad teeth,

4 Bloodgood J C Cancer of the Tongue A Preventable Disease J A M A **77** 1381 (Oct 29) 1921

areas of irritation and ulcers The same is, of course, true of cancer of the lip, gums and mouth generally

As an indication of the excellent results accomplished by the educational campaign of the American Society for the Control of Cancer, it is noted by Bloodgood that one of the large surgical clinics of this country has just completed a study of about 265 cases of areas of the tongue that were cancerous and of areas that were not cancerous In the first decade, up to 1900, but one person (3 per cent of the total number) consulted this clinic for a sore on the tongue which was not cancerous In the third decade, from 1910 to 1920, seventy-one persons, or 48 per cent, came for advice before cancer had started Since the beginning of the fourth decade, nineteen men, or 55 per cent, have, because of the educational movement, come under observation before cancer had started

Therefore, of 265 men who thought they had cancer of the tongue, in 105, or 40 per cent, protection from cancer has been accomplished by the dissemination of information only

Little [4] assumes that cancer is a constitutional disease in the same sense that premature old age is a constitutional disease, and suspects that it may be controlled by the same means, but he does not deny that chronic irritations are the usual sites for the appearance of cancer and concedes, after an interesting review of statistics, that smoking is almost a prerequisite for the appearance of cancer of the lip

It is, of course, our plain duty to encourage every effort to discover the nature and ultimate cause of cancer, but, in the meantime, no dentist or physician can justify himself in ignoring such an abundantly proven clinical or empiric fact that a man of middle age in whose mouth a quid of scrap tobacco rides habitually on a row of jagged molars, is courting disaster, regardless of theories as to whether cancer is primarily constitutional

It is the work of such organizations as the Society for the Control of Cancer which is most productive of good results in the battle against this scourge I believe that if almost any one of the men so actively and earnestly engaged in this field were asked to sum up in a single word everything that relates to our present day knowledge of cancer prevention, the one word would be "education," and although my views may be to some extent influenced by personal bias, I believe that this education should consist largely in teaching all those in middle life to exercise abundantly in the fresh air, to live in the sunshine and to subsist on a diet of fruits and vegetables as nearly as a sensible person can, and, moreover, to be sure that the foods are cooked and not eaten too hot

That overeating is not only disgusting but dangerous should be taught, and that overwork and worry lower the index of vital resistance against cancer as well as arteriosclerosis We should keep happy, employing the carefree philosophy of the negro, whose cancer incidence is low We should not smoke much, or ever use a pipe, or chew tobacco

Further education is necessary to impress physicians and the laity with the importance of recognizing precancer lesions of the skin and mucous membranes, especially when there is transition of epithelium, and dealing with them promptly Finally, all must be taught that there is no health measure more important than rigid mouth hygiene, which, after all, means to employ a good dentist and to obey him to the letter

TEACHING THE FUNDAMENTALS OF SURGERY

FROM THE POINT OF VIEW OF THE GRADUATE SCHOOL *

LOUIS B WILSON, M D
ROCHESTER, MINN

The Committee on Graduate Instruction in Orthopedic Surgery appointed by the Council on Education of the American Medical Association last year made certain fundamental suggestions concerning the training of orthopedic surgeons The first paragraph of that report [1] is as follows "This committee takes the position at the outset that orthopedic surgery is a branch of general surgery and that no preparation for the practice of orthopedic surgery can be considered satisfactory which does not comprise adequate practical training in the principles and technic of general surgery" This wise resolution no doubt explains why the chairman has asked me to talk on "the teaching of surgery" rather than on "the teaching of orthopedic surgery" What I have to say will relate to unorganized graduate medical training, to our experience in organized graduate work in the University of Minnesota, and to the lessons which may be drawn from that experience

UNORGANIZED TRAINING

Unorganized graduate training in surgery and other special fields of medicine is, of course, no new thing In this country, until recent years, most of it has been accomplished in internships, residencies, assistantships and apprenticeships, supplemented in some instances by short courses in so-called postgraduate schools either here or abroad, by visits to other clinics, and so forth We must not forget that this unorganized, somewhat hit-or-miss system has been the chief factor in the development of the present-day leaders in all the special fields of medicine It has many advantages, especially in that it permits the greatest freedom of choice on the part of the graduate student who desires to fit himself for practice in a special branch Some of its disadvantages are

1 The system is liable to waste the time of the graduate student This ill-spent time apparently averaged more than a year for each of 217 leaders in special clinical fields who responded to questionnaires of the Committee on Graduate Medical Education of the American Medical Association two years ago [2]

2 Students in surgery, when left to their own devices, are liable to strive for technical training before they have grasped the essential relationships of pathology, or have attained sufficient skill in surgical diagnosis Even their technical training may be too narrow to produce broad-gage surgeons or orthopedists

3 Interns, residents and assistants are too often selected from among the graduates of the school with which the hospital is connected These young men, without experience elsewhere, may acquire only very provincial points of view and are liable, in turn, to become members of their medical school faculty The result of this inbreeding has already shown itself, in some medical faculties, in early professional paresis

* Read before the Session on Orthopedic Surgery at the Seventy Third Annual Session of the American Medical Association St Louis May 1922

1 A M A Bull 15 49 50 (January) 1921
2 A M A Bull 14 45 49 (July) 1920

4 The failure of universities in the past to recognize by higher degrees standard attainments in special medical fields has resulted in the attempt to remedy this by such organizations as the American College of Surgeons and the American College of Physicians, which, though actuated by the best of intentions, must labor under great difficulties in any attempt to standardize large numbers of widely scattered applicants, of whose actual attainments they can have only the most superficial knowledge

MINNESOTA'S EXPERIENCE

With some realization of the above-mentioned difficulties in unorganized graduate medical training, the University of Minnesota, seven years ago, undertook to reorganize the opportunities in its laboratories and university-controlled hospitals in Minneapolis and St Paul, and in the laboratories and hospitals of the Mayo Clinic in Rochester, Minn., into a system which would provide means for selected graduate students, under advice of a competent faculty, to round out any existing weak points in their previous medical training and vacancies in fellowships available, by the long period of work required, or by the stringent educational requirements for entrance and graduation However, about 200 a year do complete their formal applications for a three to five year service, including submission of their credentials, references and so forth In all, 1,005 such complete formal applications have been filed in the Mayo Foundation A careful analysis of these applications shows that 778 candidates were eligible and 227 ineligible for admission under the rules of the university Four hundred and eighteen students have been accepted, of whom 184 have selected surgery and eight orthopedic surgery as their major field All students in orthopedic surgery have, of course, taken work in general surgery, and many students in general surgery have had special work in orthopedic surgery Hence it is proper to consider these two groups together Of these 192 students in surgery, seventy-two are either now on duty in the Mayo Foundation or have been appointed for service during 1922 Twenty-four students in surgery were permitted to resign during the first year of their fellowship, seventeen during the second year and forty-two during the third year or later, without having attempted to meet the final requirements for advanced degrees Five more are now on leave of absence Up to the present time, including the graduating class for June, 1922, thirty-seven candidates have attempted to meet the final requirements for advanced degrees in surgery Of these, thirty-one have been granted the degree of master of science in surgery, two the degree of doctor of philosophy in surgery, and four applicants have failed to meet the requirements for any advanced degree in surgery

Died

† Medical officers from the United States services fellows from other universities appointee of foreign governments et al Doe not include undergraduate volunteer summer students

Our experience during the last seven years, in interviewing and corresponding with several thousand prospective graduate medical students and in working daily with the four hundred who have been with us, has led us to make certain observations concerning the previous training of the applicants, the various means of giving those who are accepted opportunities of becoming competent in their chosen fields, and the means of testing their attainments

to fit themselves, on a broad educational basis, for practice in special clinical fields, including surgery and orthopedic surgery Accordingly, a plan for graduate medical education, which in general, follows that in operation in many universities for graduate work in the liberal arts and the other sciences, was formulated and has been in operation since Jan 1, 1915 Selected graduates of Class A medical schools who have had at least one year of graduate internship or laboratory work are accepted for periods of from three to five years of graduate work in a specific field Our seven years' experience, so far as statistics go, may be summarized thus

At present, more than 1,000 prospective candidates a year are seeking opportunities for graduate medical training in the Mayo Foundation, which is one division of the medical graduate department of the graduate school of the University of Minnesota Of these, about 60 per cent are inquiring for work in general surgery Almost all of the remainder are seeking opportunities in other clinical fields An exceedingly small number are seeking opportunities in the preclinical branches

Of the 1,000 prospective students a year, many are discouraged at the outset by the small number of

DEFECTS IN PREVIOUS TRAINING

1 Applicants for fellowships average about 27 years of age at the completion of their internship, which averages about one and one-fourth years This is obviously too old Allowing eight years for college, medical school and internship, their average age at leaving high school was about 19 years From personal interviews with hundreds of applicants, I am convinced that their retardation usually has been in the high school, and there almost always through difficulty with algebra, geometry and foreign languages All of these studies, I believe, are customarily begun after the passing of the optimum psychologic period for their acquisition I doubt very much whether 8 years of age is too early to begin the study of modern foreign languages, and I believe that every day after 12 years of age that such study is postponed adds an unnecessary burden to the student There is no question that a child of 12 can readily grasp the fundamental principles of geometry and algebra The postponement of the teaching of the principles of these until arithmetic is nominally mastered is an error which results in unnecessary hardship for the student in later years

2 Very few applicants have a real reading knowledge of French or German despite the fact that they have nominally met the Class A medical school requirements in this respect This is the result of bad teaching of the languages and the failure of medical school faculties to see that the medical student is required to persist in his reading of foreign medical literature

3 Many applicants use incorrect spoken and written English Many of them apparently have little knowledge of those subjects which contribute to good citizenship and personal culture, such as history, economics, literature, art and music Defects in these probably may be charged to their homes as much as to their schools

One cannot help believing that all such defects might be readily remedied Attention in the home to the use of correct English, to the reading of good books rather than sloppy juveniles, to training in habits of industry, persistence, promptness, honesty and courtesy should lay the foundation If, then, the grade and high schools would provide, for those whose parents desired it, instruction in algebra, geometry and foreign languages, at the period when these can best be learned, it should be possible for most boys and girls to enter college at 16 years of age Added to this, a four-year college course which includes at least as much study of the humanities as of physics, chemistry and biology, should bring the 20-year-old college graduate to the portal of the medical course, not only with more culture than he has at present, but also with much more ability to evaluate and assimilate the important portions of the several preclinical medical sciences with which he is deluged during his first two years in medical school

The attempt to teach, in the first two years of medical school, six complete medical sciences, any one of which would require the full attention of the medical student for at least two years were he fully to grasp the subject, is probably responsible for the next defect to be mentioned

4 Many applicants have but a very superficial knowledge of anatomy, biochemistry, physiology, pathology, bacteriology and pharmacy Their knowledge of essentials is as superficial as their knowledge of unessentials in these subjects

We must either double the time now allotted to the teaching of the preclinical medical sciences or halve the amount of subject matter in each which we attempt to teach if we are to approach necessary thoroughness in the essentials of each

5 Many present day graduates are at a loss to apply what they do know of the essential principles of the preclinical branches in the diagnosis and treatment of disease Unfortunately, the attitude seems to exist to some extent that, at the end of the first two years in the medical school, when the examinations in anatomy, pathology chemistry, physiology, bacteriology and pharmacology have been taken and passed, the student is through with these subjects for the rest of his life, and, now that he is no longer to be bothered with them he may give his attention to the really interesting fields of clinical medicine This attitude is so pronounced that there is a strong tendency in the last two years of medical school and during internship to permit the student to fail to apply his knowledge of the fundamental facts of the preclinical branches in his study of the diagnosis and treatment of disease

The physician who has a sufficiently thorough knowledge of the essentials of the fundamental medical sciences to use them as familiar tools in the every-day study of complicated individual cases and who threads on these lines of knowledge his careful clinical observations, until he can reach a correct diagnosis and formulate a logical plan of treatment, is unfortunately getting rarer, and his production we believe, is not favored by the present cramming system in our medical schools

SELECTION OF FELLOWS

However, with all his defects the present day applicant for graduate medical training is usually a likable and enthusiastic chap On the assumption that the limited opportunities for high grade graduate training should be given only to high grade students most likely to profit by them, how shall we determine whether a certain applicant really has the makings of a real surgeon within him? A large number of young medical students think they have such ability They are attracted toward surgery because it is the spectacular side of medicine They feel that they have a "call" to surgery This insistence of a "call on their part we should not take too seriously Dogs of almost every breed will hesitate or stop at the sight of a wild animal, but if we mistake this common hesitation for pointing, and try to train a bulldog for hunting prairie chickens or quail, we waste our time Similarly, if we try to train every medical student who thinks he is a born surgeon, we will waste our time, his time, the patient's time and, occasionally, the patient's life For this reason I doubt whether courses in the graduate school leading to the study of special fields in medicine should be thrown open unqualifiedly to every student who is able to pay a tuition fee While the judgment of faculties may be poor, they are in the long run probably much better than the ungaged desires of the average medical student who seeks admission to a graduate school for the purpose of becoming a surgeon In making selections, however, we must not be guided entirely by scholarship as recorded in the medical school and college We must look for evidence of broader scholarship than these institutions now furnish True, his scholarship in medical school should have been at least sufficient to place the candidate in the upper third of his class But, most of all, we should try to get some estimate of the appli-

cant's character Unless he shows in his personal appearance, in his manner with his associates, in his manner with patients (especially poor patients), in his general demeanor, in his honesty, his loyalty, and in his manner of receiving criticism that he is at heart a courteous gentleman, he should not be encouraged to enter an already overcrowded field of medicine If, in addition to these qualifications, he has ambition, initiative, industry, persistence and promptness, he is worthy of careful consideration for training

The candidate having been selected and means provided, either from his own funds or from private benefaction, for him to continue his special study for a period of not less than three years and preferably five, how shall his time be spent?

SERVICES IN WHICH THE CANDIDATE SHOULD BE TRAINED

Necropsy Service—At the beginning, something must be done to attempt to patch up the defects in his previous training Not all of this patching can be done at once nor should it be It is better to distribute repairs as required throughout his three to five years of training One important phase of his education has been almost always neglected in American schools He has not had his hands in more than half a dozen necropsies I firmly believe that no man should be permitted to operate on the living until he has operated on at least 100 dead Our first duty, then, if possible, is to place the embryo surgeon where he can make a start in necropsy work, which, if he is to be successful, he will need to follow out for the remainder of his professional life

At the necropsy, the student should actually make the section, beginning first as junior acting as assistant, and later as senior, making the postmortem All of this work should be done under the eye of a competent pathologist, who, as a measure of restraint, may need to tie his own hands behind his back The instructor must remember, however, that the embryo surgeon had better make errors on the dead than on the living How a sufficiently large necropsy service is to be developed even in large hospitals is, I believe, merely a question of going after permissions in a straightforward but persistent manner Time and time again, we have had demonstrations in the United States that, if we want postmortems, we can get them No hospital should be satisfied with performing necropsies on less than 75 per cent of the bodies of all patients that die Friends of the dead have as much right to demand this service as the profession has to request permission to render it

The percentage of postmortems in an institution and the character of and attendance on clinical pathologic conferences are perhaps the surest index of the scientific work of the institution

Diagnostic Service—After the necropsy service, the next in which the graduate student should be placed is the diagnosis of disease Here, under constant competent supervision, the graduate student should have an opportunity to take histories, make the simpler laboratory examinations and designate more complicated ones for all classes of patients The service should not be confined to cases that have already been separated into medical and surgical The entire grist" should be seen In this work, the most important point to be looked out for by the instructor is that the graduate student shall be compelled in his analyses of cases, to give his reasons in terms of anatomy, physiology, pathology, and so forth, that he may have constantly before him the necessity for applying the principles of these subjects in his interpretation of clinical phenomena and in his final summary or diagnosis Throughout this work and all of his subsequent work, the graduate student should be expected to attend necropsies on, at least, those patients with whom he has come in contact, and all clinical-pathologic conferences occurring in the institution

Operative Service—After not less than one year of this service, the embryo surgeon may be placed on duty as second assistant in the operating room, where his duties include the hospital preparation of patients for operation, his ordinary duties as second assistant, and the postoperative care of patients

As soon as his skill has sufficiently developed, which should be in not less than six months, and ordinarily at the end of one year, he should be given a first assistantship In our experience in the Mayo Clinic, these first assistantships are of most value to the student if they extend for a period of not less than one year under the same chief surgeon Fellows may be reappointed for a second year The student's service here may include duties outside the operating room similar to those he had as second assistant, and, in addition, he becomes to some extent responsible for the training of his junior As soon as he gives evidence of sufficient ability, he should be given opportunity to act as chief surgeon at operations, while the surgeon actually in charge stands by and sees that he does his work properly and that no harm comes to the patient

The work as thus outlined represents the principal opportunities for study which should be provided for the graduate student in surgery Nothing has been said about class work, lectures, quizzes, examinations, theses, degrees and so forth However, these all enter in their proper place

OTHER OPPORTUNITIES FOR STUDY

Lectures—I very much doubt the value of the formal routine lecture course for graduate medical students Its purpose may be better served by proper guidance in suggestive reading courses, in clinical conferences or seminars held not less frequently than once a week, and in inspiring lectures from outside men who have done special pieces of work and who may be induced to come and deliver lectures concerning it

Seminars—The seminar or clinical conference provides the best opportunity for teaching graduate medical students This is not so when the professor in charge does all the talking His function should be to answer questions rather than ask them, to stimulate discussion rather than to dominate it In other words, he should encourage his young men to form opinions and to express them, thus giving him an opportunity for kindly criticism The spirit of the seminar should be one of cooperative study rather than of master and pupil The seminar and conference should be held at a definite period of from one to two hours, not less than once a week throughout the entire course

Quizzes—How shall we know whether the graduate is making real progress? Principally, by intimate, daily intercourse with him It is desirable, when men are admitted from many different institutions, in order to test the efficiency of one's standard of admission, and to be sure that the men selected really have some knowledge of those principles of fundamental medical sciences which underlie clinical medicine, to give an examination to each man early in the course This examination, preferably, should be oral and should be

taken part in by from three to five members of the faculty, most of whom should be clinicians, who should quiz the candidate very thoroughly, yet avoid all questions except those designed to determine whether he has knowledge of the absolutely essential principles in the fundamental medical sciences. The candidate who is found not to have such knowledge should not be permitted to continue with his work. It is not the place of the graduate school to teach the elements of preclinical branches, but to give opportunity for the daily use of these elements.

Course Records.—That some record may be kept of the work of the graduate student, it is necessary that the faculty member with whom he is working shall make a report from time to time, preferably at the end of each quarter, of his work in all respects. This report should be confidential to the dean of the school and should cover not only an estimate of the details of his diagnostic and operative skill but also of his general training and his personal characteristics. Such a rating sheet, which has been in use in the Mayo Foundation and previously in the Mayo Clinic for a number of years, is presented herewith:

UNIVERSITY OF MINNESOTA GRADUATE SCHOOL OF MEDICINE

Confidential report on Fellow / Scholar in THE MAYO FOUNDATION

in Course No. with Associate / Assistant Professor

from to Major Minor

NOTE—Students will be graded A B C D or E on each numbered point on which it is possible for the instructor to form an estimate. A represents the highest possible grade and E the lowest short of complete failure. The 'General' grade for work of Course will be marked as are the numbered points or if the student's work has been a failure it will be marked F (failure) or if the student has been too brief a time with the instructor to warrant giving him a grade this item will be marked I (incomplete).

PERSONAL CHARACTERISTICS
1 Personal appearance
2 Manner with associates
3 Manner with patients
4 General demeanor
5 Ambition
6 Initiative
7 Industry
8 Persistence
9 Promptness
10 Honesty
11 Loyalty
12 Reception of criticism

TRAINING—GENERAL
13 General intelligence
14 Use of oral English
15 Use of written English
16 Chirography
17 General medical training
18 Knowledge of anatomy
19 Knowledge of physiology
20 Knowledge of pathology
21 Knowledge of medical ethics
22 Comprehension of instructions
23 Faithfulness in carrying out instructions
24 System in work

DIAGNOSTIC
25 Skill in history taking
26 Skill in physical examinations
27 Thoroughness in physical examinations
28 Judgment in referring patients for special examinations
29 Judgment in interpreting results of special examinations
30 Judgment in summarizing cases

OPERATIVE
31 Quickness of vision
32 Knowledge of and faithfulness in asepsis
33 Manual dexterity
34 Ability to meet emergencies
35 Care of postoperative cases

GENERAL GRADE FOR WORK OF COURSE

On the basis of the work which the student has done under your instruction would you recommend him for reappointment at the end of his current Fellowship year?

Would you recommend that he change his Major? If so to what?

Would you recommend that he be asked to resign before the end of his current year?

General Remarks

Date Signed

If the ordinary university grades of A, B, C, D, and so forth, are used, it is a good rule that no student receiving a grade below that of B shall receive credit toward his degree for the work so graded. It would seem to be a fair rule also that any student receiving for two consecutive periods a general grade of D or lower should be requested to leave the institution. Opportunities for grade study of medicine on a university basis are altogether too few in this country to warrant their being wasted on mediocre and inferior men.

Examinations.—Since our present system of licensing practitioners in the various states of the United States is based entirely on examinations, we are under the necessity of giving examinations to graduate students if we are to send them out from the university with the university stamp on them. As a result, all graduate students who are candidates for degrees from the university should take examinations, both oral and written, and these should be more severe in the fields of the candidate's major and minor subjects than he is ever going to get anywhere else.

STANDARD FOR DEGREES

Aside from a satisfactory residence of a definite period which should be from three to five years for the graduate study of surgery, a satisfactory record of which has been filed at definite intervals and aside from the passing of the examinations herein suggested, what other requirements should be made of a prospective candidate for a graduate degree in surgery from a university before he may be properly recommended for that degree? In the first place it appears that he must be competent in his field, in other words, he must be an 'honest-to-goodness" surgeon. The only way this can be determined as a matter of record is on certificate from the surgeons with whom he has worked that in an emergency, they would be willing to send members of their own families to him for diagnosis and surgical treatment. If they are not willing to certify to the candidate's competence to this extent, the university should not grant him an advanced degree in surgery, since the granting of this degree will stamp the candidate as a surgeon competent to care for citizens of the state.

A further qualification should be that the candidate has shown that he has a scientifically trained mind, that he is capable of analyzing and synthesizing his own observations, either clinical or experimental, or both comparing them with those of other men doing similar work, and drawing logical conclusions therefrom. Though in many respects unsatisfactory, the production of a thesis which embodies such an analysis is perhaps the best means we have for the candidate to demonstrate his scientific ability in this respect.

One of the most important services that an institution should provide is that of careful revision by members of the faculty of all articles written by graduate students. Besides this criticism for truthfulness, accuracy, clearness and so forth they should be given careful editing by a competent editor, who will then laboriously explain to the writer the reasons for the changes made. The state of our medical literature at present is most deplorable. It will not be better until we give it more thorough and more constant attention. The undergraduate medical schools should do this work, the graduate medical schools must do it.

SUMMARY

The graduate of a Class A school who has had a minimum of one year's internship in a general hospital, who has had from three to five years' opportunity for graduate work in surgery, which has included at least six months of necropsy service, one year of diagnostic service, and one and a half or, better, two and a half

years of operative service, during all three of which services he has had constantly before him the necessity for using daily the essential underlying principles of anatomy, physiology, chemistry, pathology, bacteriology and pharmacology, until they have become to him absolutely familiar tools for the diagnosis and treatment of disease, who is above all a competent surgeon, who has passed more severe examinations in the field of surgery than he will ever be obliged to pass elsewhere, and who has prepared and defended a thesis of the character indicated, may properly be recommended for the degree of master of science in surgery or master of science in orthopedic surgery, as the case may be, to be granted by a properly constituted university of which the medical school is a part

Besides the foregoing, it sometimes happens, though unfortunately not often, that a graduate medical student shows that he has real research ability and demonstrates this beyond peradventure by making an actual contribution of considerable import to medical science For such a student, there should be reserved the degree of doctor of philosophy in surgery or orthopedic surgery Of course, in addition to the requirements outlined for the master of science degree, he should fulfil also those other minor conditions, particularly in relation to foreign languages, which are ordinarily required by universities of candidates for the degree of doctor of philosophy in other fields

CONCLUSIONS

I wish to urge the importance of graduate work in surgery, orthopedic surgery, or any other specialty being done in institutions where work in other fields of medicine is going on at the same time Isolation, in the long run, is a serious handicap The daily association of men who are engaged in other fields, the discussions with them in informal conferences and, especially, the frank criticisms of each other in staff meetings at which are read the articles which are the results of scientific study in the institution, all conduce to a much broader view of a specialty and to the making of much broader men who are to practice in the specialty

ABSTRACT OF DISCUSSION

DR DEAN LEWIS, Chicago The training of the surgeon is a timely but rather large subject for discussion It seems rather a reflection upon surgeons that a pathologist should apparently consider it necessary and eminently fitting that he should outline the courses of graduate instruction necessary to make a well rounded surgeon and then pass upon his qualifications Dr Wilson has discussed the graduate training and as this rests upon a sound and sufficient undergraduate training, I consider that I shall not be digressing from the discussion if I mention some of the things in undergraduate work which are necessary to the proper training of a surgeon In the first place men graduate too late in medicine They should graduate much earlier so that they may devote their early productive years in concentrated effort upon the work which they choose to follow The second feature which militates against good training is the lack of cooperation of departments and coordination of teaching It should be possible to establish a curriculum which will give the best preparation, but this will never be possible until department heads are willing to sacrifice for the common good The curriculum and methods of instruction in vogue today are of the spoon feeding type There is too little effort made in the development of critical analytic ability and to discourage the acceptance of any dogma laid down notwithstanding insufficient data upon which deductions are made We constantly hear about the teaching of principles If a student in surgery had spent a few hours in this section yesterday afternoon, I do not believe that he would have been able to unravel the skein of principles involved in the treatment of fractures It is not so long ago that the operative treatment of fractures threw into the discard most of the thoroughly established principles of the treatment of fractures which are just now being rescued This merely shows how enthusiasm and propaganda can overthrow old established principles It is difficult to say how the sound principles of surgery can be preserved when enthusiasm unchecked by critical ability and sound reasoning is rampant No one denies the necessity of a sound pathologic training but how to stimulate the student in the study of pathology is a great question I would make the surgeon an excellent diagnostician, an expert pathologist, a good physiologist and an expert and sound operator This is a difficult thing to do and it requires years of preparation A man must be an idealist to secure the training necessary to fit him for the practice of surgery, and he is often discouraged in finding that he is handicapped in the competition discovering frequently that surgery is sold to the highest bidder Fee splitting interferes more with the training of the surgeon than the limitations of the students or the imperfections of our medical schools and clinics

DESENSITIZATION OF HAY-FEVER PATIENTS BY INJECTION AND LOCAL APPLICATION*

A H W CAULFEILD, M B
TORONTO

The localized desensitization which may take place after one has produced a reaction in testing a patient against pollens or proteins has been outlined by MacKenzie and Baldwin[1] Their preliminary experiments showed the degree and duration of the cutaneous exhaustion which might follow an initial test At this time they anticipated "the probability that by local application of pollen or dandruff extracts to the mucous membrane of the nose and throat of patients with allergic rhinitis the reactivity might here also be abolished"

The observation on my part, that specific cutaneous sensitization might disappear over night from a very considerable part of the same forearm which previously had been tested and found positive, led me to consider the possibilities of applying therapeutically the principles underlying the phenomenon This change in local reactivity was drawn to my attention by the more or less routine testing of both bronchial asthmatic and hay-fever patients, and was not followed up by a series of carefully controlled experiments such as were made by MacKenzie and Baldwin

In selecting ragweed as the particular pollen with which to try local application, I was influenced by the fact that it is with the ragweed-positive cases that one experiences the greatest difficulty in obtaining satisfactory desensitization and freedom from clinical symptoms The possibility of further influencing the reactivity of the mucosa by utilizing local application as well as by subcutaneous injection would appear to be the logical basis on which one would expect the

1 MacKenzie G M and Baldwin L B Observations on the Specific Exhaustion of Cutaneous Reactions Proc Soc. Exper Biol & Med 18 214 1921 Local Desensitization in Hay Fever Individuals and Its Bearing on the Prevention of Hay Fever Arch Int Med 28 722 (Dec) 1921 MacKenzie, G M Desensitization of Hay Fever Patients by Specific Local Applications J A M A 78 787 (March 18) 1922

clinical results to be associated In this connection it is to be remembered, however, that patients may show after successful subcutaneous treatment either positive or negative cutaneous sensitization to the pollen or protein against which they have been injected In any event, the data which might be obtained from locally applying the antigen to the mucosa seemed sufficient to justify its trial on general, as well as on therapeutic grounds

The introductory references to the literature by MacKenzie [2] are so similar to those which had appealed to me as relative to the subject that I feel I may omit this aspect beyond perhaps drawing attention to the observations by Besredka [3] that the introduction of antigen through the upper respiratory tract is a satisfactory means of inducing immunity, and that through this channel also it is possible to induce anaphylactic shock in properly sensitized guinea-pigs Parker's [4] demonstration that ragweed has true antigenic properties seemed to favor the selection of this pollen for the evaluation of local application and for any further work which might be suggested by the observations attendant on its application locally

The groups of patients summarized in Table 1 suffered from seasonal hay-fever, they were tested and found positive to different pollens which, in view of the seasonal character of their symptoms, afforded reasonably certain evidence that their symptoms were due to pollen sensitization In estimating the number of seasons involved, previous experiences were disregarded unless the pollens indicated by such past experiences gave positive reactions Patients will not infrequently state that previously they suffered from symptoms which began in early summer and continued till the late autumn, but that latterly symptoms had begun only with the onset of the autumnal variety, the reverse of this, namely, an increase in the seasonal duration of symptoms, is perhaps as frequent

The cases taken for analysis include all those treated except (1) a few who have failed to reply to inquiries regarding the results experienced, and (2) a number whose injections were far too few to warrant any conclusion being drawn therefrom A certain number have been included to whom the full course of treatment was not given, because they either began too late or were absent during periods of their treatment A rigid adherence to only those who had taken a full course previous to the approximate date of onset would exclude a number who experienced very satisfactory results

Local application was made by inunction, the ragweed pollen being ground up (mechanically), and quantitatively mixed with phenolated petrolatum in dilutions [5] of 1 2, 1 20 and 1 200 Each dilution was put up in collapsible tubes, and applied by expressing a convenient volume on the little finger of the patient, and thoroughly rubbing into the nasal mucosa

MacKenzie obtained local application by spraying the mucosa While this would seem to have the advantage of reaching a greater area, a number of small considerations led me to select inunction The dose was increased by mixing varying proportions of two strengths on the finger in advancing from the first application of the 1 20 strength to that of the 1 2 strength, for example

METHOD OF GENERAL AND LOCAL DOSAGE

Injection [6] was given twice weekly except in the few instances in which the local reactions [7] were sufficiently severe to warrant a temporary postponement During the prophylactic treatment the inunctions were made in nearly all cases at the time the injection was given in a few the inunction was made by the patient at home a day or so following the subcutaneous treatment The preseasonal treatment was, as far as possible, planned so that the full course would be finished sometime during the week or ten days following the date of onset of the patient's seasonal type In suitable cases after the completion of the injections, tubes of the 1 2 strength of ointment were given to the patient for a limited continuance of local application The number of pollens against which desensitization was attempted in each case is shown in Table 1 The factors on which this was decided were the degree and relative sensitization, as shown by the cutaneous tests, the history of seasonal symptoms, and the time available for treatment The frequent absence of relative cutaneous sensitization, as exhibited by different patients, between, for instance, the various grasses used in testing and among these the occasional absence of a positive test to either timothy or red top pollen, has led me to believe that treatment on the assumption of group reaction will not be as satisfactory as treatment based on the tests, repeated preferably during the season of attack This conclusion is supported, among others, by Watson and Kibler [8]

In planning early in 1921 a trial of local application I had intended to use alternate cases so that afterward the results could be compared with those obtained by injection alone As my experience with it increased, such a plan of comparison was abandoned, and the combined method was used in the majority of cases because of one or another of these considerations

1 The combined method gave me the impression that dosage could be more rapidly increased with less local,

4 Parker, Julia T The Antigenic Properties of Ragweed Pollen Proc Soc. Exper Biol & Med 18 237 1921

5 These *frictions refer to* that dilution of a stock concentration of 1 70 This method was used so that the dilutions in ointment should correspond to the amounts used in the solutions made for injection

6 All pollen solutions were put up in four dilutions of the stock solution which was made up by grinding 1 gm of pollen in 70 c c of diluent These extended from a 1 20 000 dilution to a 1 10 Occasionally a 1 4 solution was made and used A preliminary desensitizing dose of 0 2 5 c c was given from a 1 200 000 solution (of the pollen or pollens to be used) at each treatment If for any one treatment more than one pollen was used the amounts from the different solutions desired were all drawn into the syringe before injection With some attention to detail it was nearly always possible to keep the total volume below 1 c c and at the same time give the different solutions desired at the time

The rate of increase was judged by the reactions caused by the previous dose on which the following rules might be taken as approximate guides A If no local reaction was induced in either arm (from the desensitizing or therapeutic injection) the dose was increased four to five fold or more depending on circumstances B If a local reaction was induced in one arm only (therapeutic injection) the dose was increased from two to four times depending on the severity of the reaction C If a local reaction was induced in both arms the increase should be slight and under twice N B 1 The greatest care must be exercised as one nears the more concentrated solutions 2 Particularly after more than one large increase in the dosage without local reaction extreme caution should again be used as it is apparently possible suddenly to overstep the threshold and induce an almost instantaneous general reaction without the warning of having obtained local reaction

7 For the comparatively few instances in which a general reaction has followed the injections given as outlined I have always found epinephrin of immense value I believe it should always be available Given hypodermically in from 0 5 to 1 c c doses it is often startling in the rapidity of its effect The subject of reaction should I feel not be mentioned without emphasizing its dangers—even that of death R A Cooke in a comprehensive discussion of this aspect (Studies in Specific Hypersensitiveness J Immunol 7 119 145 [March] 1922) both endorses epinephrin as the best drug available and advocates strophanthin in selected cases In my four years experience with pollen and protein desensitization I have had only two instances of a delayed general reaction of any severity in both of which the approximate guides suggested in these remarks were for different reasons ignored

8 Watson S H and Kibler C S Etiology of Hay Fever in Arizona and the Southwest J A M A 78 719 (March 11) 1922

and less tendency toward a general reaction than by injection alone 2 The season last year was advanced, and one was pressed for time in which to achieve prophylactically the amount of desensitization desired 3 Considerable guidance with regard to dosage was afforded by the absence or degree of nasal reaction to the injection 4 Treatment could be continued, i e, dosage increased by local application if the patient was forced by circumstances to miss the injection Under these circumstances, the combined method was used in most of the difficult cases

The small number of cases and the modifying circumstances in many instances would seem to justify impressions rather than statistical studies of the respective value of the methods of desensitization outlined in this paper Comparative evaluation of their therapeutic effectiveness with that reported by others is rendered difficult because of the lack of uniformity in the classifications adopted with regard to the degree of protection obtained In consequence, the definitions which follow—and have been used in this paper—are an attempt to suggest a set of classifications which combine certain features common to previous publications, and which are compatible with the divisions suggested by my own experience

1 Complete freedom, to include, as well, those who reported an occasional transient attack of sneezing or nasal moisture, or an occasional prodrome, not realized symptomatically The intervals, constituting practically the entire season, are to be without symptoms Estimated value, from 90 to 100 per cent

2 Practical freedom, to include those who were able to continue all their occupations or exercise (train, golf), with no prolonged attacks (part of a day only), and those infrequent, or one short series of more or less continuous mild attacks, following which freedom to be complete Estimated value, 75 per cent

3 Marked benefit, to include those who experienced attacks, but none to compare with their former experience and to have had long periods of freedom, may or may not have continued their vocation or avocations Estimated value, 50 per cent

4 Slight or no benefit, to include those whose relief was less than that defined in the third class

5 Aggravation, to include those who obtained no benefit and whose symptoms were seemingly worse than formerly experienced This fifth class may suit the results obtained in certain cases, particularly in view of the varying severity of seasons in different years, but for practical purposes groups 4 and 5 may be considered identical

The patients in Table 1 have been grouped according to seasonal type, and in the results of treatment column for last year each season has been considered separately Because a greater proportion of the cases (those that were ragweed positive, that is) were given the combined treatment, the results obtained previously have been utilized as a type of control

The column labeled "difficult" refers to the manner in which the patient responded to increase in dosage If the necessary increase, because of the imminence of the time of onset, induced sufficiently severe reactions to retard the desired progress, the case at once became in varying degrees difficult to treat The degree in which this occurred is approximately shown by the use of the plus sign

In the comment column, the observations have been confined to bronchial asthma as an all season complication, if due to proteins as shown by appropriate tests, or to bronchitis if severe "Late" means that only to a limited extent was the treatment preseasonal "Interrupted" and "incomplete" refer to the course of treatment "Out of town" means that the course was completed by cooperation with others living outside Toronto In varying degrees these factors militate against the best results, and hinder satisfactory comparison

TABLE 1—ANALYSIS OF CASES

Case No	Seasons: Spring	Seasons: Summer	Seasons: Autumn	No. of Pollens Injected	Injections Only	Combined Treatment	Difficult	Therapeutic Results: Previous Year	Therapeutic Results: Last Year	Post Treatment Sensitization	Comment

40			+	3		+	+++		4	++	
41			+	9		+	++		2	?	
42			+	2		+			3	+	
43			+	3		+			1	—	

The sign + signifies a marked cutaneous reaction the sign ? a reaction of doubtful degree (from 4 to 6 mm) the sign — no reaction or one less than 4 mm the sign 0 that post treatment tests were not made The figures under column Therapeutic Results refer to the foregoing classifications

In the first group of three cases, five seasons were completely free and one season practically free, in which latter the treatment was only partially prophylactic all the higher dilutions being given during the earlier part of the season The third patient suffering throughout all three seasons illustrates a mild type of autumnal attack in contrast to the spring and summer The previous year, fairly severe symptoms developed in September after a free spring and summer Tests done then showed ragweed and goldenrod to be positive both of which had previously been negative

In the second group (summer hay-fever only) there are five instances of complete freedom, one of which was obtained the previous year and last year remained free without treatment In the two remaining cases, which were practically free, the treatment could not be regarded as ideal, as one patient was late and treatment was continued during the season, while the second was to a great extent out of town

In the third group (combined summer and autumnal variety) there are, as regards the summer type, six instances of complete freedom out of six cases treated last year, the case with complete freedom during the previous year remaining free last year without treatment As regards the autumnal type, there are two instances of complete freedom, three of practical free-

TABLE 2—DEGREE OF PROTECTION

	Group 1 (Spring Included)	Group 2 (Summer Only)	Group 3 (Summer and Autumn)	Group 4 (Autumn Only)	Number	Per Cent	
Complete freedom	2	5	3	10	20	46 5	
Practical freedom	1	2	3	8	14	32 6	90 7
Marked benefit	0	0	2	3	5	11 6	
Little or no benefit	0	0	0	3	3	7 0	9 3
Aggravated	0	0	0	1	1	2 3	
Total	3	7	8	25	43		

dom and one of marked benefit In these less satisfactory results, the factors militating against success such as lateness, interruption and incompleteness, are noticeable Four cases were treated by the combined method, and despite difficulties in treatment, and the factors as noted in the last column, two complete and two practical "reliefs" were obtained

In the fourth group (twenty-five cases of the autumnal type) twenty-two cases were treated last year, among which there are nine instances of complete and six of practical freedom, three patients obtained marked benefit, three slight or no benefit, and in one case the symptoms were aggravated Success was jeopardized by the poor opportunity for treatment in one of the three obtaining only marked benefit, and as well, in two of the three with no benefit No such explanation, however, can be advanced as a cause for one case of no benefit, and for the case which was aggravated, but which the previous year was completely protected

Table 2 summarizes the degree of protection In this the results for each season are not taken into account as they were in *Table 1, the most unfavorable* outcome being taken as indicative of the protection obtained

Local application was employed with twenty cases out of the thirty-three in Groups 3 and 4 These numbers are obviously too small to serve as a basis for any conclusion, moreover, the different circumstances militating against a fair trial were too frequently present in both the injection and combined treatment groups Without attempting to assess these varying factors, the percentage results obtained show that the combined treatment in contrast to injections alone was slightly more successful The figures for combined treatment versus injection alone respectively are in complete freedom 45 and 30 7 per cent, in practical freedom 35 and 30 7 per cent, in marked benefit 10 and 23 per cent, and in no benefit, including aggravation, 10 and 15 3 per cent

In Table 1, the results of sensitization after treatment have been noted because a consideration of these suggest that, when this is marked, the combined treatment may be contraindicated An attempt was made to ascertain the correlation between the cutaneous and the nasal reactivity in a few cases The contrast afforded among these cases so tested showed a fairly marked degree of similarity, when one considers the relative character of the amounts used and the difference in the methods used to elicit this Apart from any theoretical considerations, an analysis of the degree of post-treatment sensitization and the therapeutic results show that in both Groups 3 and 4, there were six cases treated by the combined method in which the post-treatment sensitization was marked The results in these were three of no benefit, including the one case of aggravation, two of marked relief, and one of practical freedom This proportion of poor success or failure is greater than in the other treated by the combined method, and also greater than that obtained in similar cases treated by injection alone Admittedly, the numbers are too small, but the effect at least raises the question of the advisability of using local application in those cases in which previous tests have shown marked cutaneous sensitization after injections alone, especially if the results obtained had been satisfactory

The conclusions drawn by MacKenzie, using a different method of local application by itself, combined with and contrasted to hypodermic injections alone, left me with the impression that he considered its further use justified My results lead me to concur with the restriction that it may be contraindicated in certain individuals

OBSERVATIONS ON THE DISTRIBUTION OF VITAMIN B*

SAMUEL R DAMON, PH D
BALTIMORE

The absolute necessity of an adequate supply of vitamin B, in the dietary of growing animals, if growth is to be maintained at a normal rate, is a fact that has been established beyond question Among the earlier observations on this point were those of Osborne and Mendel,[1] Hopkins[2] and Stepp[3] These authors, working independently, arrived at the same conclusions, although their ideas as to the nature of the hypothetic substance were at variance Since that time, research has led to the demonstration of vitamin B in "milk, rice, wheat embryo, cotton seed, pancreas, maize kernel, wheat, oat, kidney beans, yeast, ivy beans, peanut meal"[4] and many plants used as food in the form of 'greens," such as asparagus, celery, dandelions and lettuce[5]

An adequate supply of vitamin B is necessary not only because of the growth stimulating properties of the vitamin itself but also because of its influence on the general food intake of the animal[6] All experimenters in the field of accessory food substances have observed the stimulating effect of an adequate vitamin supply on

the appetite of their animals These substances need be present in only minute quantity, but their presence is essential It is this relation to appetite and food intake that prompts this report

In the course of certain studies on bacterial nutrition it became of interest, at one time, to test the basal ingredients of culture medium of organic origin, i e, peptone and beef extract, for their vitamin content This research was especially indicated, since the literature is not clear on this point Bayliss,[7] in his discussion of the growth promoting principle "Bios," says "It is present in Liebig's meat extract and commercial peptone" Funk[8] reports the presence of vitamin in meat juice and meat extract and Osborne and Mendel[4] as well found "a small amount of the water soluble food hormone" in meat extract

EXPERIMENTAL METHODS USED

The tests were carried out on young rats, weighing from 50 to 75 gm, which were failing to grow on a diet known to be adequate to promote growth at a normal rate when sufficient vitamin B was supplied The food mixture consisted of casein, 18 per cent, sugar, 17 starch 52 5, butter fat, 10, and salt mixture, 2 5 Inspection shows this mixture to be adequate except for the deficiency of vitamin B

The peptone and beef extract were added to this ration in place of definite quantities of starch Each substance was tested in the amount of 2 5 and 7 5 per cent of the ration

RESULTS

In no case was the decline of the experimental animals stopped by the addition to the ration of definite quantities of either peptone or beef extract

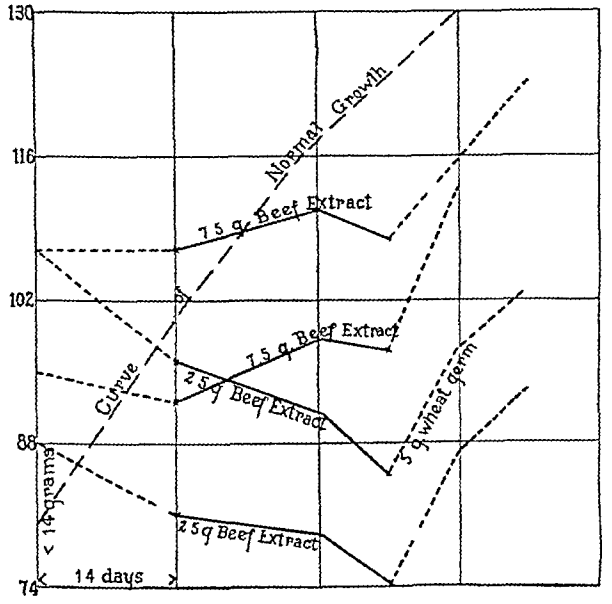

Chart 1.—Failure of rats that had declined on a diet deficient in vitamin B to recover when beef extract was added as a source of this factor

The accompanying charts show typical growth curves of rats fed this experimental ration The initial period of decline, on a diet deficient in vitamin B, is indicated by the dotted line Following this is the period when the animals were fed the same basal ration plus the peptone or beef extract and failed to recover, and finally there is the period of recovery, indicated by the rapid rise of the growth curve when the basal ration was supplemented by wheat germ as a known source of vitamin B

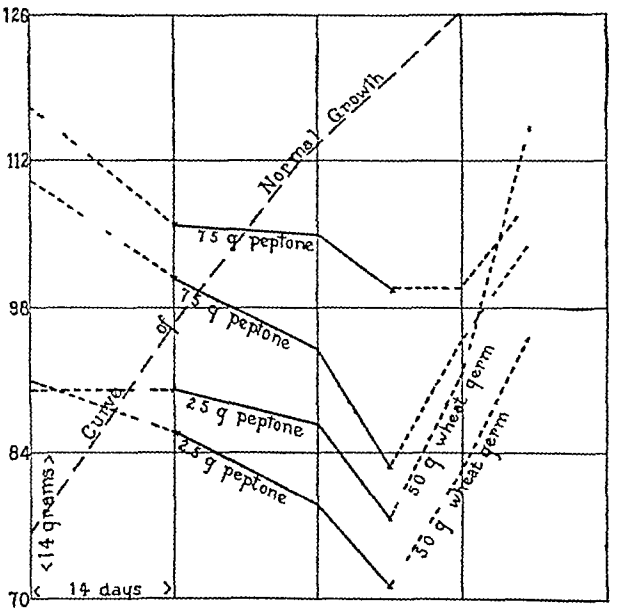

Chart 2.—Failure of rats that had declined on a diet deficient in vitamin B to recover when peptone was added as a source of this factor

CONCLUSIONS

Commercial beef extract and peptone are devoid of the water soluble vitamin B

NOTE.—The importance of these observations in connection with the use of beef extract in convalescence will be recognized by all who heard Dr Mendel at the recent Congress of American Physicians and Surgeons in Washington describe the relation of vitamin B to appetite and food intake

THE PRACTICAL APPLICATION OF THE RESULTS OF VITAMIN STUDIES

L. EMMETT HOLT, M.D.
NEW YORK

Our knowledge of vitamins has given a new basis for the evaluation of foods Certain articles which, from the point of view of their energy value, are almost worthless have been shown to possess great nutritive value Their importance is not suggested by their chemical analysis They furnish something very essential in a human diet

The tomato, cabbage, spinach, lettuce, chard and all the green or leafy vegetables are composed chiefly of cellulose, water and inorganic salts Fruits have sugar, vegetable acids, water and salts, but none of these things suggest their essential value as foodstuffs

Many of our foods we no longer eat in their natural state The conditions of modern life have made necessary the transportation of foods for long distances and the preservation and storage of food in immense quantities for long periods A certain amount of injury is done to our vegetables, fruits, milk, meats and grain by the processes to which they are subjected in preparation, preservation and storage The study of vitamins has helped us to understand, to some degree at least

7 Bayliss W M Principles of General Physiology 1915 p 260
8 Funk C Munchen med Wchnschr 1913 p 2614

the nature of that injury Some of it is due to the heat applied during our ordinary processes of cooking, some is a consequence of heat applied for purposes of sterilization, whether for the destruction of the germs of disease or for the preservation of food

We have also sacrificed something in their nutritive value by the refinement of our foods, as in polishing rice and using only the white flour of our wheat to make our bread, and feeding to pigs and cows the balance of the grain The coarse black bread of the middle ages and of the European peasant of today is despised by our modern civilized city dweller

But let us not at the same time forget the immense benefits of the preservation and storage of food Take, for example, the question of white wheat flour As long as wheat was grown and milled, as it still is in most European countries, within a comparatively short distance of the place where it was consumed, and was used within a few weeks of milling, the problem was a simple one *At present much of our milling is done* 1,000 or 2,000 miles from our large centers of population Not only must the time required for transportation be taken into account, but also the necessity for storage of immense quantities as a normal food reserve New York City, for instance, consumes more than 20,000 barrels of flour every day Much of this, it is estimated, has been milled five or six months before it is eaten White wheat flour keeps indefinitely, certainly for many months, without any important deterioration But whole wheat flour can be kept only about thirty days, after that it is likely to become "wormy" Flour experts tell us that the general adoption of whole wheat flour for bread in this country is an economic impossibility The modern method of milling and our system of transportation and storage make a bread famine here almost impossible

Although heating milk may injure or destroy its vitamins, this fact does not invalidate its great advantages, such as protection from diseases which may be communicated through milk and its preservation by drying, condensing or sterilizing, which permits its wider use as a food all over the world The same may be said of the canning and drying of vegetables, fruits and eggs These preserved foods are all of great benefit in the nutrition both of children and of adults We would not stop the use of them if we could

Our knowledge of vitamins has, however, pointed out that these procedures have their disadvantages, even their dangers, but when the nature of these is once thoroughly understood and their importance appreciated, the remedy will come also

In the food of infants it is only vitamin C that is likely to be injured by any process to which their food, chiefly their milk, is subjected in preparation or preservation In the first place, it should be understood that the amount of this vitamin in milk is small Chick and Hume found that, to protect a guinea-pig, whose food contains no other source of this vitamin, 100 c.c. daily of fresh milk is required, although complete protection is secured by only 1.5 c.c. of orange juice

It is well established that all heating of milk (I do not, of course, mean warming for feeding) whether by boiling, pasteurizing, sterilizing, drying or condensing, injuries this vitamin It has not been shown that vitamin A or vitamin B in milk is thus injured The amount of injury done to vitamin C depends on the height of the temperature and the length of the period during which the temperature is maintained, and possibly on whether the heating is done in open or in sealed vessels The duration of the heating seems clearly more important than the temperature employed Short heating at a high temperature apparently does less injury than prolonged heating at a lower temperature, so far as its effect on this vitamin is concerned, boiling for five minutes seems better than pasteurizing for thirty minutes

While there is still considerable difference of opinion among investigators as to the relative amount of damage done by various types of heating, it may be regarded as proved that they all injure milk in this respect, and that the only safe rule in practice is to supply some efficient antiscorbutic in the diet of all infants reared on milk treated in any one of these ways

Evidently the body has a sufficient store of this vitamin to meet its needs for a considerable time for symptoms of scurvy do not usually appear for some months after the deficient diet has been taken Of *the last nine cases of infantile scurvy treated in my* hospital service, the period was between five and seven months in seven, and in none more than nine months

If the food contains even a small amount of antiscorbutic vitamin, the development of scurvy will be delayed To infants whose principal or sole food is any one of the forms of heated, dried or condensed milk, it would appear, then, to be quite sufficient if an antiscorbutic were begun at the age of 5 months

The observations of Hart, Steenbock, Ellis and others indicate that the vitamin content of cow's milk is affected by the food of the animal This was first shown to be true of the vitamin C The winter milk of stall-fed animals was decidedly poorer in this respect than the summer milk of pastured animals The same law seems to hold with respect to all the vitamins If the food of the cow does not contain an adequate supply, the milk may be deficient in any or in all of them It would seem, therefore, a wise precaution during the winter to supplement cow's milk by other foods known to be rich in this vitamin such as the yolk of egg or the juice of steamed green vegetables, but best of all by cod liver oil

The vitamin content of the food of the nursing mother undoubtedly affects her milk in a similar way This may furnish a clue to some of the puzzling cases of scurvy developing in nursing infants

It is reported that, among the Filipinos, beriberi is common among the nursing children of rice-eating mothers of those islands This is believed to be a large factor in the extremely high infant mortality that is seen there

These facts may explain why infants do not thrive on some milks, although the supply is abundant and the proportion of the different constituents, as shown by chemical analysis, is within normal limits

The practical application of these facts is, first, to recognize the necessity of supplying to nursing mothers a diet which is ample in all the vitamins Vitamin A and vitamin C are the ones most likely to be lacking in the diet of the poor These vitamins are abundantly supplied by milk, eggs, green vegetables and fruits, all of which unfortunately are expensive foods but should be included in the diet

I have never seen and have never known of a case of scurvy in a child over 2 years old who was living under normal peace conditions So far as vitamin A —so indispensable for the growth of children—is concerned, it is necessary only that care be taken that the

diet include an ample supply, since it is not likely to be injured in the preparation or preservation of food

We know well the dangers of vitamin deficiency when the diet is necessarily restricted, because conditions do not admit of choice or variety of food These conditions exist in times of famine or great food shortage, or even may be the result of poverty, also in prisons, army camps, on shipboard, in the arctic regions and, one must add, in infancy The consequences to children are serious, whether we consider simply arrested growth and general malnutrition or the diseases, such as scurvy and beriberi, which result from marked and prolonged deficiencies But it does not seem probable that, except in conditions like those mentioned, either children or adults who take the average or usual diet are likely to receive such small quantities of the vitamins as definitely to interfere either with growth or normal nutrition

A glance over the list of foodstuffs known to contain the different vitamins shows how abundant vitamins are in most common foods This may be one of the reasons why, in the evolution of the diet of the human race, certain foods have a place It seems perfectly evident that, unless the diet given is a very one-sided one, children receive in their usual food a liberal supply of all these essential food constituents

Two very striking things are brought out in the investigation of vitamins by observations on animals One is the very small amounts which are apparently required to produce their effects, and the other is the specificity of their action

Until these substances have been isolated, we shall not know the amounts required for normal nutrition Apparently, the amount of any one of them is not large

Chick, Drummond and their associates at the Lister Institute have shown how much of different foods is required to protect laboratory animals against beriberi and also against scurvy, when the diet contained no other source of the vitamin in question While this establishes much that is important with regard to the relative value of foods, it gives us no idea as to the actual amounts required by human beings All the evidence goes to show that the vitamin requirement is affected by many conditions It undoubtedly varies even in animals Laboratory animals in confinement might be expetced to show effects of deficiencies in diet sooner than those living under natural conditions It is well known that men who were much exposed and doing hard work were affected by scurvy sooner than others, although all had the same diet If the human diet is poor in other respects, the effects of the absence of the antiscorbutic or any other vitamin is more quickly apparent

How much of the different vitamins is needed for health we do not yet know It is clearly not a definite amount for all human beings of the same age, sex and weight, but, like our other food requirements, the vitamin need no doubt varies with many conditions

The great importance of vitamins for growth makes it imperative that the diet of children especially should contain the articles of food that are rich in these factors The requirements of adults are for maintenance merely and undoubtedly are much less than those of children This is especially true of vitamin A

It is during the period of infancy that children are likely to suffer most first since infants are the most susceptible of human beings to all adverse conditions, secondly, infancy is the period of most rapid growth, and anything which may affect growth produces its most marked effects at this time, and finally, the diet of infancy is necessarily a restricted one

Proprietary foods are harmful, not so much from what they contain as from what they lack They may be deficient in all three of the vitamins

The specificity of action of these substances is quite as great as that of antitoxin in diphtheria or thyroid extract in cretinism The different vitamins seem entirely independent of one another in their activity They are in no way interchangeable, they seem to have no relation to one another We cannot supply a deficiency in vitamin B by giving more of vitamin A, nor can we protect against scurvy by the most liberal allowance of vitamin B Each one has a perfectly definite function in nutrition, which, from all evidence now in our possession, can be performed by it but by nothing else

If no vitamin deficiency exists in the diet, it does not seem probable that general symptoms of malnutrition in children past the period of infancy who are taking a varied diet are due to a deficiency of any of these factors, or that improvement in general nutrition is likely to follow their administration in larger amount, when no real deficiency exists In other words, benefit from an excess of any of them seems most improbable, and we lack proof that such is the case

Another practical question is whether if the diet is low in its vitamin content, i e, a condition of relative deficiency exists, there may occur perhaps not frank scurvy, beriberi, rickets or keratomalacia, but milder and less definite symptoms, such as failure to make normal progress in growth malnutrition and general evidence of ill health This is something difficult to establish On *a priori* grounds it seems not improbable It must be remembered, however, that symptoms such as those mentioned may be due to a great variety of causes other than vitamin deficiency In the absence of definite means of diagnosis, the only evidence of their dependence on vitamin deficiency is the therapeutic test, namely prompt and decided improvement, which follows when foods known to be especially rich in the different vitamins are added to the diet—such as orange juice or yeast or cod liver oil

Reasoning from experience with deficiency diets in animals, one would expect to see improvement in a few weeks In this connection one is reminded of the "patent medicine" advertisement which ran somewhat as follows 'If you are not cured you haven't got the disease The remedy never fails"

It should first be evident from an analysis of the diet that a deficiency probably exists The changes made should be as carefully planned as are laboratory experiments with rats or guinea-pigs Otherwise the results reported to follow are likely to depend on either the faith or the skepticism of the observer

Some suggestive observations on the use of antiscorbutic vitamin have been made by Hess and others, in which the weight curve of infants showed a prompt rise on addition of orange juice to the daily diet, but in many or most of these cases the diet was known, or at least strongly suspected, to be poor in this factor

Vitamin B has been urged upon the profession in the form of yeast as being especially important for children who are not making the normal gain in weight, who suffer habitually from poor appetite, chronic constipation, etc My own experience has been one of complete disappointment

However, in view of the important part which we now know to be played by vitamins in nutrition, it behooves the physician in all cases of malnutrition, particularly when the explanation is not obvious, to investigate carefully the character of the food and its preparation to discover any errors that might result in a vitamin deficiency Especially is this necessary in the case of chronic invalids or of delicate children whose diet has become greatly restricted from necessity or from caprice, and in the case of infants, whose diet is always a restricted one But, until we have some more certain means of diagnosis than we now possess, the indiscriminate use of vitamins in other circumstances than the foregoing for what is often referred to as "general results" is not likely to be beneficial, it should be discouraged It is hardly scientific therapeutics

It is most unfortunate that the popular interest in vitamins, which is the result of so much recent publicity as has been given to this whole subject, should be exploited commercially Just now vitamins are in fashion and as much capital as possible is being made of this fact The medical profession, at all events, should not be carried along in the popular current Important and indispensable though vitamins are, one can fall into no greater error than to assume that vitamin deficiency is the chief cause of all chronic nutritive disorders, just as not very long ago these were all referred to autointoxication, and at present a certain group would have us believe that they are due to some disturbance of the glands of internal secretion The use of vitamins without definite indications will be popular for a period but, like other fads, it will pass With time and further investigation, their true place will be determined

Our knowledge of vitamins has taught the necessity of a variety of food and the danger which follows when conditions make a choice of variety impossible It has taught us also the incomparable value of certain foods, particularly of milk, not only in infancy, but during the entire period of growth, also the importance in the diet of children of the green or leafy vegetables The chief objection to some, such as cabbage, lettuce and celery, when used in a raw state is the difficulty of making children masticate them properly

Our knowledge of vitamins has greatly helped to put the whole subject of nutrition on a scientific basis The experimental method has been substituted for the empiric one in determining the value of the different foods Formerly we might know that certain foods were desirable or necessary, now we are able in very many cases to say why such is the case and to determine their precise value in nutrition A knowledge of vitamins has furnished a key to many problems in nutrition which before were obscure or insoluble

Until they have been confirmed by clinical experience there is, however, some danger in relying too much on the results of laboratory observations on animals of a different species, whose physiologic needs may be different from those of human beings

The study of vitamins has taught us several important things regarding the nutrition of children

Children should eat a variety of food, and special dangers may follow the habitual use of a very restricted diet

Milk is the one indispensable food for children The diet during the entire growth period should include, if possible, whole milk, or if skimmed milk is used it should be supplemented by butter Of the butter substitutes, those which contain beef fat, mutton fat and peanut oil are better than those in which other vegetable oils or lard are important constituents

A diet which includes no milk whatever should contain ample amounts of the green or leafy vegetables

Cereals, particularly those from whole grains, and potato are important and adequate sources of vitamin B

Fruits have other uses than as laxatives and as sources of mineral salts, they should form a regular part of the diet When fresh fruits are not available, dried fruits may be given, but they are distinctly inferior to canned tomatoes as sources of the antiscorbutic vitamin

Cabbage is such a rich source of all the vitamins that it should form a larger part of the diet than is usually the case, especially since it is cheap, and in winter often almost the only green vegetable available

In normal peace conditions, the results of vitamin deficiency are most often seen in infancy In rare cases they may be seen in older children and in adults when there is extreme poverty, and still less frequently in those suffering from chronic disease, or in very delicate children whose diet for a long period has been greatly restricted

If the daily diet contains in reasonable amount unskimmed milk, cereals, potato, green vegetables and fruit, one need not fear a vitamin deficiency While these articles are especially rich in vitamins, nearly all of our common foods contain them

CLOSTRIDIUM BOTULINUM

II PRESENCE IN THE HUMAN ALIMENTARY TRACT *

FRED W TANNER, PH D
AND
GAIL M DACK
URBANA, ILL

The importance of *Clostridium botulinum* as a cause of food poisoning, and probably food infection, justifies extensive study of its distribution At frequent intervals it has been reported in the intestinal contents of both apparently healthy and diseased animals and human beings The present paper is a report of a short study on its possible presence in the intestinal tracts of healthy human beings

Van Ermengem [1] isolated the organism from the intestinal tracts in fatal cases of the disease In 1897, however, he could not find it in the intestinal contents of fish, or in cow or horse manure, or duck excreta Burke [2] found the spores of this organism in insect droppings and manure from a hog which had recovered from botulism three months before Dickson [3] examined the intestinal contents of 250 hogs without finding the organism in a single instance Kempner and Pollack [4] isolated it in 1897 from the intestinal contents of a hog We [5] found it in three specimens of hog feces and one sample of sewage Graham and Barger [6] found *Clostridium botulinum,* Type A, in one specimen of feces and five specimens of urine from

* From the Department of Bacteriology, University of Illinois

widely separated spontaneous cases of poliomyelitis in Illinois Graham and Schwarze [7] isolated the organism from the intestinal contents of chickens that had died of limber neck

In order to determine whether the spores of the organism might be present in the intestinal tract of the healthy human being samples of stool were collected from ten different persons

TECHNIC

Ten samples of feces from apparently healthy persons were brought to the laboratory on sterile swabs The samples were broken up in sterile physiologic sodium chlorid solution and transferred to sterile corked test tubes These were shaken vigorously for about ten minutes on the shaking machine in order to secure a homogeneous preparation The tubes were then put into a constant temperature bath at 80 C for thirty minutes in order to destroy the vegetative cells which were present Various qualitative dilutions were made and the material was plated out in dextrose agar The plates were made anaerobic by Dick's method After incubation at 37 C, the plates were carefully examined for colonies like those of *Clostridium botulinum* Suspicious colonies were transferred to sterile tubes of sheep brain medium which were incubated at 37 C after being made anaerobic with sterile paraffin The sheep brain medium cultures which gave the characteristics of growth generally secured in this medium were tested serologically for the presence of the botulinus toxin One cubic centimeter portions were fed to guinea-pigs by mouth Those animals which died with the usual symptoms were examined postmortem and new cultures in brain medium were inoculated with material from the brain of the guinea-pigs It has been found that the organism may be isolated from the brains of guinea-pigs which have died with a typical case of botulism This culture was then carefully purified and typed against antitoxin kindly supplied by Prof Charles Krumwiede

RESULTS

Two of the ten specimens of feces from apparently healthy human beings were found to contain the organism Five others gave very strong evidence of its presence The cultures from these five samples, however, formed weaker toxins, and death in the guinea-pigs was delayed for as long as twenty days in one instance The guinea-pigs, however, died with the usual symptoms at the end of that time This delayed death has also been mentioned by others Since these strains reacted so sluggishly to the usual tests, they were not regarded as absolutely positive, although we feel that they were *Clostridium botulinum* An analogy may exist between the delayed symptoms in guinea-pigs and those in human beings It is possible that some of the severe gastro-intestinal disturbances often occurring in isolated cases and in groups may have been due to a weak toxin capable of causing symptoms only superficial to those caused by a strong toxin Perhaps the incubation period in some of these cases may be so delayed that the apparently spontaneous symptoms, when they appear, are not connected with the ingestion of a poison-containing food

The significance of these data is perhaps merely suggestive Our results seem to be somewhat confirmed by the more recent contributions on the presence of the organism in the soil Tanner and Dack [8] and Meyer and Geiger [8] have shown that the organism is quite widely distributed in the soil The latter investigators have proposed that certain geographic areas may be more heavily seeded than other areas It would not be unexpected to find the organism on foods which are eaten fresh or which are partially or imperfectly cooked An analogous situation seems to exist in *Clostridium tetani* The work of Nicolaier and others [9] has shown that this organism is abundant in the superficial layers of the soil, and especially in soil which has been cultivated and fertilized The recent work on forage poisoning [10] by a number of investigators also indicates that the organism may be distributed in soil and may thus reach food In the numbers that would get into food its presence is probably not significant Armstrong Story and Scott [11] reported that pigs receiving 120 000 000 spores subcutaneously died in four days, while animals receiving 12,000,000 and 1 200 000 spores remained well Orr [12] has given this subject more elucidation While Orr admits the possibility of toxemia due to the ingestion of detoxicated spores, he regards it as of very rare occurrence, if it ever occurs Thus, it seems that the spores of *Clostridium botulinum* may be present in the intestinal tracts of apparently healthy persons without any untoward symptoms or results

SUMMARY

Two of ten specimens of feces from healthy persons were found to contain *Clostridium botulinum* Five other specimens gave strong evidence of its presence The two strains absolutely identified as Type B strains formed powerful toxins in sheep brain medium

DIAPHRAGMATIC HERNIA AS A LATE SEQUEL OF WAR WOUND OF THE CHEST

HAROLD E WAXMAN, M D PITTSBURGH

An interesting phase of the case here reported is the fact that diaphragmatic hernia may be confused with appendicitis From a theoretical standpoint it scarcely seems probable that a condition pathologically and anatomically so different from diaphragmatic hernia as acute appendicitis could be confused with the former Yet this did happen, and Borden [1] recently reported a similar mistake although in a widely different and more chronic form of diaphragmatic hernia

REPORT OF CASE

History—J B, a white man aged 28 a city fireman, was admitted to the hospital, Dec 30 1920, complaining of pain in the abdomen December 23 while at a fire, the patient was overcome by smoke He did not remember much of what had happened to him, but was told by companions that his asphyxia was rather profound, and the pulmotor was used Before the accident, to the best of his knowledge, he was in perfect health That evening he began to have a dull pain in the left side of the abdomen just below the ribs The pain radiated upward to the left shoulder The pain was not severe He took no medicines and abstained from food, as part of the after-treatment of the asphyxiation His bowels moved well that day without causing him any pain or other symptoms, and so continued until December 26, three days after the accident The dull pain in the left hypochondrium

persisted December 27, he began to have pain of a dull nature in the right iliac fossa The onset of this was followed by vomiting Since then he had vomited at all attempts at eating The vomited material usually consisted of what he had eaten shortly before He had not had a bowel movement since December 26, and numerous enemas proved unsuccessful December 30, he developed acute, agonizing pain in the right iliac fossa, the pain on the left side having subsided Realizing that his condition was not due altogether to the asphyxiation, he again called his physician, who advised immediate removal to the hospital

When admitted, he complained only of a sharp, colicky pain in the lower right abdomen and of vomiting whatever food or drink he took He had not secured a bowel movement for four days in spite of the use of enemas On the morning of admission, hiccup developed and persisted He said that the vomiting was almost always preceded by a long period of nausea, which he relieved voluntarily by forcing the act of vomiting when it did not come spontaneously

The patient said that he had always been active and athletically inclined, enjoying excellent health He had all the usual minor ailments of childhood, but none of the more serious acute infectious fevers In 1918 while in action in France, he was wounded 'just below the heart" by a machine gun bullet He was in a military hospital for several months No exploratory operative treatment was attempted at the time he was shot He apparently made a good recovery, and said that he had been in excellent health since his discharge from the army He had never before had any pain of a nature similar to that which he was now experiencing He had never had a surgical operation of any kind

Examination—On the left side of the chest, in the midclavicular line, in the sixth interspace, was a scar from the entrance of the bullet There was also a scar at the point of exit of the bullet in the left posterior axillary line, in the tenth interspace The heart and lungs were normal The abdomen was flat, with no distention, and was tympanitic to percussion above the umbilicus There was marked tenderness on deep palpation over the entire right iliac fossa, with some rigidity of the right rectus muscle No tenderness was noted elsewhere, and no masses were palpated There were *no hernias, inguinal or femoral* Rectal examination was negative The specific gravity of the urine was 1 030, examination revealed albumin, trace, sugar, negative, indican, trace, casts, none, red blood cells, a few Blood examination revealed leukocytes, 15,000, polymorphonuclears, 77, small mononuclears, 17, large mononuclears, 6

Clinical Course—December 30, the patient's condition was as described in the history A diagnosis of acute intestinal obstruction, with probable location in the right iliac fossa, was made Exploratory laparotomy was urged, but the patient refused his consent The temperature ranged between 99 and 100 F

December 31, a marked changed in the patient's condition was manifest He was restless, and complained of great pain in the right iliac fossa During the twenty-four hours since admission, four irritant enemas had been given These were returned practically as given, uncontaminated with fecal matter The abdomen was distended uniformly There was exquisite tenderness and marked rigidity of the overlying musculature of the right iliac fossa The breath had a fecal odor Operation was accepted The diagnosis was acute appendicitis or intestinal obstruction

Operation and Result—Under ether anesthesia, a right lower rectus incision was made The cecum, ascending colon, transverse colon and terminal ilium were markedly injected and greatly distended The appendix was bulbous, infiltrated, bound down, and surrounded by a small quantity of pus Considerable manipulation and exploration were necessary to locate the obstruction of the intestine accounting for the distention The splenic flexure of the transverse colon was caught in a small hernia of the diaphragm The incision was, of course, in the wrong place to deal effectively with both the appendical condition and the diaphragmatic hernia The patient was in great shock The knuckle of bowel was hastily freed from the opening in the left diaphragm, and the abdomen closed The operation was performed by a member of the visiting staff

The patient did not rally through the night from the shocked condition in which he left the operating table In spite of all restorative and stimulative measures, he died, twelve hours after the operation

COMMENT

To have made a diagnosis of diaphragmatic hernia would have been easy enough had this been a case in which the patient did not present an acute condition of the abdomen, if there had been sufficient eventration of the abdominal contents into the thorax to give physical signs, or if a roentgen ray examination could have been made In this case the optimum in diagnosis would have been acute intestinal obstruction With the presence of pain in the right iliac fossa there seems some justification for having regarded the seat of all trouble in that location Had an incision been made in the upper left quadrant, it might also have been possible to deal secondarily with the appendical condition, but, as is too often the case, in this instance "hindsight seems better than foresight" Undoubtedly, also, operation was too long delayed

The explanation of the mechanism of production of the hernia may be that, during the violent breathing which the patient undoubtedly employed while overcome by smoke, through greater use of the abdominal muscles in respiration the increase of intra-abdominal tension was sufficient to rupture the scar in the dome of the diaphragm on the left side and force through the splenic flexure The accompanying acute suppurative appendicitis beggars explanation It gave a justification for making the right iliac fossa the location suspected as being also the seat of the acute intestinal obstruction

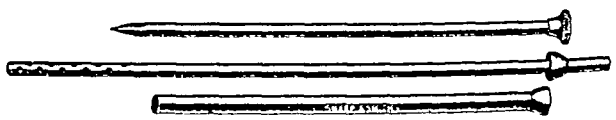
A PRACTICAL TROCAR AND CANNULA FOR REMOVING ASCITIC FLUID

WILLIAM W DUKE M D KANSAS CITY, MO

When ascitic fluid is withdrawn from the peritoneal cavity through the cannula ordinarily used for this purpose, the end of the cannula frequently strikes loops of intestine or the omentum before the desired amount of fluid has been removed This not only interferes with further withdrawal of fluid, but causes pain and anxiety in the patient The



Trocar and cannula for removing ascitic fluid at top trocar, in center inner cannula at bottom outer cannula

end of the cannula can be freed from the intestine or omentum by manipulation, and additional amounts of fluid can be withdrawn Such additional amounts, however, are usually small, and after manipulation has been attempted several times, further effort at complete drainage has to be abandoned The result is that a considerable amount of ascitic fluid may be left in the peritoneal cavity This may drain through the wound made by the cannula for one or several days, and cause the patient much annoyance This disadvantage can be overcome by the use of the double cannula shown in the accompanying illustration

The outer cannula consists of a metal tube 9 5 cm in length with a bore 4 mm in diameter This is fitted with an ordinary trocar The trocar and outer cannula can be introduced into the peritoneal cavity in the usual manner, the trocar can be withdrawn, and in its place the inner cannula with the blunt, perforated end can be introduced The inner cannula is 13 5 cm in length, with a bore 3 5 mm in diameter This cannula, on account of its length and blunt end, can easily be introduced deep into the pelvis without causing

pain or anxiety in the patient The flow of fluid cannot be obstructed easily by omentum or loops of intestine, and the result is that the peritoneal cavity can be drained almost dry without difficulty The advantages of this cannula would appear to offset its only disadvantage, namely, slightly increased cost

YEAST PREPARATIONS

Report of the Council on Pharmacy and Chemistry

At its 1922 meeting, the Council directed that a general article, giving the present status in medicine of yeast and yeast preparations, be prepared A committee was appointed for the purpose This committee submitted to the Council the report which appears below, with the recommendation that its publication in THE JOURNAL and its subsequent inclusion in N N R be authorized The Council adopted the report of the committee, and, accordingly, the article, Yeast Preparations, appears below W A PUCKNER, Secretary

Yeast and preparations from it have long been used both externally and internally in medicine Yeast, as commonly understood, is the ordinary brewer's or baker's yeast, consisting of the minute unicellular organism *Saccharomyces cerevisiae* These cells have long been characterized by their power to convert certain sugars into products of fermentation, a reaction in which enzymes present in the yeast are concerned

So-called dried yeast is usually obtained by filtering off the yeast cells grown on extracts of malted grains, they are completely or partially dried and may, or may not contain a considerable admixture of starchy substance Lately, preparations of relatively uncontaminated dried yeast have been marketed Some of the dried yeast preparations are intended to retain their fermentative power In others this has been destroyed by the process of desiccation The so-called compressed yeast sold in freshly prepared form, usually with some admixture of a starchy substance to give it a suitable texture, will retain its fermentative activity for several days when kept at a low temperature To what extent other micro-organisms are likely to contaminate the commercial yeast preparations is not generally known

Actions and Uses—Since fermenting liquids, if concentrated enough, have been assumed to have a bactericidal action yeast has been proposed for use as a bactericide in the treatment of infections of the superficial tissues Its application for this purpose has, however, been practically abandoned, although there are traditional accounts as to the healing properties of fresh yeast applied to open wounds As yeast is one of the richest sources of vitamin B, which has recently come into prominence as a hitherto unrecognized food component essential to nutritive well being and widely distributed in common foods, yeast and preparations derived therefrom have been widely extolled of late as sources of this vitamin whenever there may be indications for its therapeutic use The latter are still so indefinite, aside from rather exceptional instances, such as beriberi, and the opportunities to obtain vitamin B through the customary foods entering into the dietary of man are so abundant that the special demand for the yeast vitamin seems to be limited relatively at the present time At all events, the alleged curative or tonic value of special vitamin B bearing products has been emphasized through widespread advertising to an extent unjustified by available evidence The beneficial effect of products containing vitamin B on animals subsisting on a diet deprived of this food factor is truly remarkable, but this fact attested by laboratory observations, should not be interpreted to mean that there is a widespread avitaminosis in this country or that the need for vitamin, other than in exceptional cases, cannot readily be supplied through simple dietary measures The therapeutic aspects of the vitamin problem are still in the experimental stage

The ingestion of yeast in liberal portions is known to produce a laxative effect In some cases particularly in young children such use of yeast has been followed by intestinal distention, doubtless attributable to fermentative gas production by the surviving yeast cells There is, however a preponderance of evidence regarding the advantageous use of yeast as a mild laxative Aside from the objectionable possibility just referred to, there are no serious contraindications Whether the laxative action of yeast is due to the survival of the living cells and some product of their reaction in the intestine or to a chemical component of yeast which may also be present in dead cells is not clear at present Yeast has often been recommended for internal administration because of its supposed beneficial effects on furuncles, acne, etc Its adherents assert that it is almost a specific Many, if not most, clinicians doubt this remarkable effect which may after all, be expected from any anticonstipation agent Whether yeast or its products can provoke a leukocytosis likewise remains undemonstrated Many of the conditions for which yeast and yeast preparations have been recommended therapeutically are so variable in their clinical course and so likely to show improvement without special treatment that the elaborate claims made in regard to yeast therapy for somewhat indefinite disorders must be largely discounted It is not clear to what extent, if at all live cultures of yeast may be used to change the intestinal flora, if, indeed such a reaction becomes desirable in many of the conditions for which yeast is commonly used

Concentrated liquid extracts of yeast (which are rich in vitamin B) have long been used as substitutes for meat extracts in making bouillons and soup stocks, and it is asserted that meat extract is sometimes adulterated with yeast Yeast vitamin concentrates have been prepared from extracts of yeast by a variety of methods

---

THE FOLLOWING ADDITIONAL ARTICLES HAVE BEEN ACCEPTED AS CONFORMING TO THE RULES OF THE COUNCIL ON PHARMACY AND CHEMISTRY OF THE AMERICAN MEDICAL ASSOCIATION FOR ADMISSION TO NEW AND NONOFFICIAL REMEDIES A COPY OF THE RULES ON WHICH THE COUNCIL BASES ITS ACTION WILL BE SENT ON APPLICATION W A PUCKNER, SECRETARY

ANTI-ANTHRAX SERUM (See New and Nonofficial Remedies, 1922, p 284)

Parke Davis & Company, Detroit

Anti Anthrax Serum Marketed in syringes containing 50 Cc. (*Bio 45*) Initial dose of from 50 to 100 Cc injected intravenously should be followed by further injection in six or more hours It is well to test the sensitization of the patient to horse serum prior to the first injection by means of the cutaneous test which will require about one half hour The drop of serum required for this test can be obtained directly from the syringe container of Anti Anthrax Serum

ANTIMENINGOCOCCUS SERUM (See New and Nonofficial Remedies, 1922 p 286)

Parke Davis & Company, Detroit

Antimeningococcic Serum Marketed in packages of two syringes with flexible connection gravity tube and needle with stylet (*Bio 170*) each containing 15 Cc also in packages of one syringe with needle and long flexible tube suitable for intravenous injection either by pressure or gravity method (*Bio 172*) each containing 50 Cc

Dosage—From 50 to 150 Cc intravenously from 15 to 30 Cc. intraspinally

DIPHTHERIA ANTITOXIN-TOXIN MIXTURE (See New and Nonofficial Remedies, 1922, p 282)

Parke, Davis & Company, Detroit

Diphtheria Toxin Antitoxin Mixture—Diphtheria Prophylactic Each cubic centimeter of the mixture represents a single human dose corresponding to the requirements of the Public Health Service Marketed in packages of 3 bulbs each containing 1 Cc (*Bio 60*) representing one immunizing treatment also in vials containing 20 Cc (*Bio 65*)

TUBERCULIN DENYS (See New and Nonofficial Remedies 1922 p 296)

Parke, Davis and Company Detroit

Tuberculin B F (Bo inr)—Made in the same manner as tuberculin D nys (Human) except that the bovine type of tubercle bacillus is used Marketed in packages of six 1 Cc sealed glass tubes

Borcherdt's Malt Extract (Plain) (See New and Nonofficial Remedies, 1922, p 176)

Borcherdt s Malt Cod Liver Oil and Prosphorus Each 100 Cc. contains phosphorus, 0 009 Gm (1/25 grain per fluidounce), cod liver oil 25 Cc and Borcherdt s malt extract (plain) 75 Cc.

Dosage—From 8 to 15 Cc (2 to 4 fluidrachms) three times a day after meals

FEBRILE TEMPERATURE

The current conception of fever involves reactions which consist in an alteration of the body temperature, together with changes in the mechanism which controls this temperature Fever can be induced by placing the body in an environment so warm and moist that heat cannot be lost by the usual devices of radiation, conduction and evaporation In such a predicament there is an obvious failure of heat elimination In persons suffering from ichthyosis hystrix involving an almost complete loss of function of the sweat glands,[1] the body temperature can be varied by altering the temperature of the surroundings Considerations such as these have been responsible for the view that a prominent factor in the genesis of fever is the failure of the mechanisms ordinarily responsible for the removal of heat from the body On this hypothesis the increment of heat might be merely an exaggeration of that seen in healthy persons after exercise, but with an imperfect elimination of the heat thus set free

Water is of so much importance in heat loss by vaporization that one naturally thinks of the rise in temperature as possibly dependent on a failure or inability of the body to "mobilize its water reserve" As stated in a recent article,[2] the ability of the body to utilize water in heat elimination is of the greatest importance in the regulation of temperature Because of its high specific heat and fluid character, it is capable of absorbing large amounts of heat from the cells and of distributing it to the surface of the body, where it may be eliminated The dry skin and concentrated urine of acute fevers has often given rise to the belief that the mechanism of heat loss is disturbed

The latest studies of Du Bois [3] and his colleagues, in a variety of infectious fevers, lend no support to the theory of inability of the body in such conditions to mobilize its water reserve for the elimination of heat Their results show that the heat lost in the vaporization of water from the skin and lungs bears a fairly constant relationship to the total heat elimination In cases of erysipelas, for example, the heat lost in the vaporization of water constitutes from 23 6 to 33 4 per cent of the total heat elimination During rising, constant and falling temperatures, the percentage of heat eliminated in the vaporization of water was greater than in normal persons, hence the conclusion that fever should not be attributed to failure in the function of water elimination

The careful earlier calorimetric investigations of typhoid, tuberculosis and malaria are now supplemented by additional evidence from other febrile states to show that rise in body temperature is accompanied by increased heat production, and that the increase corresponds to the degree of fever Apparently the patient with fever responds to bodily changes by a rise in temperature in a manner which resembles closely the chemical reactions in the test tube suspended in a water bath According to Barr, Cecil and Du Bois, the increased heat production follows van t Hoff's law, which may be thus stated "With a rise in temperature of 10 C, the velocity of chemical reactions increases between two and three times" This means an increase of from 30 to 60 per cent for a rise in body temperature from 37 C to 40 C It is important to realize that increment in body temperature may of itself thus "speed up" metabolism

THE GOETSCH TEST IN HEALTHY PERSONS

Medical practice is enriched and mankind benefited by any procedure, prophylactic, diagnostic or therapeutic, by which the problems of disease can be more accurately approached When Sir John Floyer adapted the watch for the counting of the pulse, he made the civilized world his debtor The application of chemistry in the test for sugar in the urine has proved to be of enormous help to the physician The simplified technic for the estimation of basal metabolism has opened new possibilities in clinical medicine Human nature is not always easily swayed by interest in the novelties of science, but, when it is moved, the pendulum of enthusiasm is often more than likely to swerve too far in one direction before it regains the normal swing One need but read the history of any new test, new instrumental procedure, new apparatus or new drug, to find abundant illustrations of this dictum

The epinephrin test introduced by Goetsch for the detection of hypersensitiveness in hyperthyroidism [1] seems to be no exception to the common experience referred to It depends in principle on the theory that,

1 A good description of the procedure is given by Wearn J T and Sturgis C C Effects of Injection of Epinephrin in Soldiers with Irritable Heart Arch Int Med **24** 247 (Sept) 1919

in an organism in which there is an overabundance of thyroid secretion, the sympathetic nervous system is sensitized to the action of epinephrin Peabody and his collaborators [2] at the Peter Bent Brigham Hospital, Boston, have already ascertained that, although hypersensitiveness to epinephrin as measured by the Goetsch test is found in many persons showing the clinical picture of hyperthyroidism and an increased basal metabolism, yet it is not always present under these conditions On the other hand, the Goetsch test may show a positive response in persons who have no other indications of hyperthyroidism

Significant evidence of this has lately been offered by Van Wagenen,[3] who conducted Goetsch tests on a group of students in the Department of Physical Education at Cornell University He states that "a more physically fit, more symptomless group could not have been desired" Yet in the fifty persons comprising it there were ten positive reactions, or 20 per cent, judged by the characteristic changes in blood pressure, pulse rate, general symptoms and local reactions attending the intramuscular injection of the conventional test dose of epinephrin hydrochlorid Such facts raise doubt, to say the least, as to the exclusive diagnostic value of a test for hyperthyroidism in "borderline cases" in which, in the absence of observable symptoms of psychoneurosis, neurasthenia and hysteria, so large a proportion of healthy persons respond in what might be designated as a positive way

REJUVENATION BY TESTICULAR TRANSPLANTATION AND OCCLUSION OF THE SEMINAL DUCTS

The quest through the ages for a mystic agent which shall revive the faded youth of the aged has recently been rewarded—at least so the newspapers allege—by the discovery of the fountain of youth Indeed, two such fountains have been acclaimed from different sources Neither of the methods proposed, it is true, promises more than partial rejuvenation of the old Neither offers, for example, to grow natural teeth to replace artificial dentures, or to garnish a bald pate with a luxuriant thatch Yet, if a method will renew sexual vigor—and this is the alluring promise—full many a Faust will eagerly barter his worldly goods for drafts from the fountain

The more sensational of the two methods of rejuvenation now in the limelight is the transplantation into the old man of testicular substance removed from young men, monkeys, goats or whatever the market affords Each of these sources of material is guaranteed, by somebody, to rejuvenate A fundamental error in this scheme is the assumption that vigor in general and erectile power in particular are measured solely by some testicular internal secretion, and hence that loss of such power can be remedied by a fresh supply of testicular substance Physicians know that destructive disease of the thyroid, of the anterior pituitary or of the suprarenal cortex entails loss of sexual power as surely as does castration, that copulative vigor is apparently a composite, possible only when a chain of endocrine glands, including at least those just named, furnish their normal products to the blood, and that under-function of any of these impairs vigor in general, and virility in particular Removal of the entire thyroid, for example, causes sexual impotence, relieved not by transplanting testes but by feeding thyroid tissue Since a chain is no stronger than its weakest link, and since in old age all the links of the endocrine chain are weaker than in youth, it is difficult to imagine that the implantation of youthful testicular substance could rejuvenate old men, any more than that the insertion of a new link could strengthen a worn-out chain The legitimate subject for testicular implantation, by this reasoning, is the otherwise normal young man whose testes have been destroyed by disease or injury In some such cases, however, this attempt has failed utterly, but in a few other cases, disinterested physicians have attested an improvement, general and sexual, following the transplantation of human tissue In no instance, so far as we know, has an alleged rejuvenation of an old man been so attested

A second assumption in this scheme of rejuvenation is that transplanted gonad substance, of whatever origin, continues to function in its new environment Yet in many instances human tissue, testicular and ovarian, removed months after such transplantation, has been found to have been treated as a foreign body, disintegrated and removed by the tissues of the host The clinical results of gonad transplantation, as reported by the operators themselves, range from flat failure to marvelous success, thus, the gonad of the goat is said to have cured or mitigated not only sexual impotence but also a score of chronic ailments of diverse etiology and pathology The veteran Tuffier whose surgical utterances have long commanded respect, working in a Paris hospital with the precision of a laboratory investigator, implanted ovarian tissue freshly removed from young women into each of twenty women who had passed the menopause, in not one of these was there a return of menstruation or other evidence of rejuvenation Most of his 230 operations were autotransplantations, removal of ovaries from the pelvis to other locations in the same woman The results illumine the subject under discussion, for, while menstruation was reestablished in a majority of the women under 30, in only one of fifty-six women over 40 did this flow reappear after autografting Moreover, even in the youngest women, from four to ten months elapsed after autografting before men-

2 Peabody F W Sturgis, C C Tompkins E M, and Wearn J T Epinephrin Hypersensitiveness and Its Relation to Hyperthyroidism Am J M Sc 161 508 (April) 1921

3 Van Wagenen W P Some Observations on the Epinephrin Hydrochloride Test (Goetsch Test) in a Group of Normal Individuals J Indust Hyg 3 343 (March) 1922

struation was reestablished, and, when it did appear, it was irregular and seldom continued more than three years His verdict is that the therapeutic result of autografting of ovaries is transient, that of grafting from one woman to another is nil It is difficult to reconcile such facts with the copulative frenzy alleged to occur in old men a few days after implantation of human or other testes, except through mental suggestion No work on testis transplantation so convincing as Tuffier's ovarian transplants has come to our attention

A second widely advertised method of rejuvenation emanates from a Vienna physiologist, Steinach This scheme likewise measures vitality solely in terms of testicular secretion, but claims to increase such secretion in an old man, not vicariously, through transplanted gonads, but directly, by speeding up his own production The blood supply of the testis is normally divided between the spermatic tubules, which provide sperms for procreation, and the interstitial groups of epithelial cells called Leydig's glands, which are supposed to elaborate the internal secretion Steinach assumes that, by diminishing the production of sperms, there must result an increased blood supply to the interstitial glands and a corresponding increase of internal secretion, whereupon the old man is young again A decrease in sperm production is known to follow gradually the occlusion of the seminal duct, hence the Steinach method is simply vasectomy or its equivalent Some physicians harbor the idea that Steinach devised a method or operation disclosing a new principle, the only novelty was the occlusion of the seminal duct by dividing the vasa deferentia leading from testis to epididymis instead of the vas itself and the motive for this was the hope of sparing the artery of the vas deferens, the smallest of the vessels supplying the testis, which is necessarily ligated in vasectomy But since Steinach asserts that identical results followed simple vasectomy in senile rats, and since the Vienna surgeon who applies the theory to human subjects abandoned the so-called "Steinach operation," the Steinach thesis is reduced to simply this Occlusion of both seminal ducts rejuvenates an old man Although the flaws in this argument are glaring and numerous, their enumeration is superfluous, because there is overwhelming clinical evidence that occlusion of the seminal ducts does not rejuvenate an old man A generation ago, when prostatectomy was more dangerous to life than it now is, vasectomy was widely practiced for the mitigation of the evils entailed by prostatic obstruction, leaders in surgery, including Harrison in Liverpool and Rovsing in Copenhagen, reported the results in hundreds of cases of bilateral vasectomy for this purpose in old men, in not one was rejuvenation achieved In a recent article, a Steinach follower, apparently realizing that the latter's scheme for rejuvenation died before it was born, naively explains that the old men vasectomized a generation ago did not secure rejuvenation because they were not expecting it! Apparently, then, occlusion of the seminal ducts increases testicular secretion only when the old man is convinced in advance that he will be rejuvenated It should be possible to induce such conviction without resorting to surgery

Current Comment

MEDICAL ETHICS

One factor distinguishing medical from other professional ethics is that medical ethics relates largely to acts immediately affecting the lives and health of human beings, and not to merely abstract principles This distinction has been recognized, since the days of Hammurabi, in all statements of principles, or so-called codes of medical ethics It is interesting to note too, the permanence of the statements of ethical principles governing specifically the acts of physicians, as formally approved by the American Medical Association, since the adoption of the "Code of Ethics," at the first annual session of the Association, in 1847 The code then adopted continued in effect until 1903, when, at the New Orleans session, it was superseded by a new statement there adopted, and the title changed from "Code" to "Principles" of medical ethics, but even then only minor modifications were made, the most important being the omission of the chapter defining the relationship which the public and the patient should hold to the practitioner of medicine In 1912, the statement of the "Principles of Ethics" was revised, but the changes were hardly more than changes in phraseology New conditions, however, have recently developed in the practice of medicine, and group and institutional practice have loomed up as elements to be reckoned with Many physicians, it is to be feared, have quite unconsciously tolerated on the part of groups and institutions with which they are connected acts which they would not for a moment have considered if they had felt that they individually were responsible for them It has always been recognized, for instance, that "solicitation of patients" is unprofessional and that a physician cannot ethically engage in such solicitation Justice and fairness demand that the practice be not indulged in by physicians through groups or institutions with which they may be connected, any more than it would be indulged in by such physicians acting in their individual capacities These considerations led the House of Delegates at the last annual session in St Louis to incorporate in the "Principles of Ethics" the following, so that there might be no doubt as to the duty of groups and institutions or of the physicians connected with them

> SEC 4—Solicitation of patients by physicians as individuals or collectively in groups by whatsoever name these be called or by institutions or organizations, whether by circulars or advertisements, or by personal communications, is unprofessional This does not prohibit ethical institutions from a legitimate advertisement of location, physical surroundings and special class—if any—of patients accommodated

As may be noted, it is recognized that "institutions" which provide means for treating the sick and which have certain physical attributes which can properly be

announced may call attention to these facilities But groups of physicians associated for any reason, in group clinics or other institutions, should conform to the restrictions governing the individual physician For professional and quasiprofessional acts committed by such groups or institutions, the physicians connected therewith must hold themselves accountable

A SCHOLASTIC VIEW OF BOTULISM

A critical attitude of mind toward generally received opinions is perhaps a desirable character in an adult, zeal for propagation of the faith—one's own faith—is also often considered commendable But a combination of the two qualities sometimes produces results that make the judicious grieve An editorial comment on 'More 'Botulism'" in a recent number of the *Medical Officer*, London (June 10), is an astonishing example of the effects of mental prejudice In reviewing an article[1] that appeared in THE JOURNAL on an outbreak of botulism in Cambridge, Idaho, the writer of the editorial quotes the list of foods eaten at the fatal meal, and goes on in somewhat questionable taste "We are not told if the water was home-canned Anyway, the birthday party, although no doubt an immediate success, was tragic enough in the conclusion" The concluding paragraph of the editorial reveals an imperviousness to scientific evidence which is so extreme as to be diverting

> But the diagnosis of 'botulism" in these days does not cut much ice We are so familiar with the 'trailers" that follow and the "scouts" that precede our influenza epidemics with all the symptoms of 'sausage poisoning" that we are chary of accepting that unconvincing and unaerobic bacillus which Van Ezmergen [Van Ermengem is doubtless meant] "discovered" twenty odd years ago It is so much more probable and likely that all the reported examples of so called botulism were case-to-case, and not food infection, that they were examples of stupor, of lethargy, of polio-enceplado-myelitis of encephalitis lethargica—call them what you will At any rate in this instance we feel that there is some possibility of excusing the home canned food, nor is this the first time that epidemiologists have been nauseated by the insistence by avid writers on their discovery of new and rare diseases

The view so confidently and naively expressed in this paragraph is held by a small but scriptorially active group in England This is not the place for a critical discussion of the somewhat tenuous hypothesis that would attribute influenza, epidemic encephalitis, botulism and poliomyelitis to a single 'epidemic constitution" But we can at least point out that the airy dismissal of botulism as a figment of the imagination has never been preceded by any serious critical discussion of the numerous comprehensive investigations of botulism carried out in this country during the last decade Before such immature views as those expressed in the *Medical Officer* can receive anything more than indifferent and amused attention, they must be based on something more substantial than innuendo and scholastic word-juggling The grotesque misconceptions about botulism shown by the writer of the editorial cited, indeed, the sheer ignorance of epidemiologic and bacteriologic evidence, do not encourage much confidence in the speculations that are responsible for the attempt to deny botulism a place in the list of specific affections Such views as expressed are all the more reprehensible, appearing, as they do, in a publication devoted to the enlightenment and interests of public health officials

Association News

BUREAU OF LEGAL MEDICINE AND LEGISLATION

Complying with the request made by the Council on Health and Public Instruction, the House of Delegates of the American Medical Association, at the St Louis Session, authorized the Board of Trustees to take over from the Council its medicolegal and legislative work and to organize a bureau through which such work shall be carried on The Board announces the appointment of Dr William C Woodward as Executive Secretary of the Bureau Dr Woodward's experience in public life, as health commissioner of the District of Columbia and later of Boston, and his legal training have especially fitted him for the position

The functions of the Bureau of Legal Medicine and Legislation are (1) To keep in touch with federal and state legislation relating to medicine and public health, (2) promptly and intelligently to advise interested state associations and component societies concerning medical legislation and, so far as practicable, to cooperate with them in such proper action as they may take, (3) to study the circumstances under which threatened actions for malpractice arise, with a view to devising methods, if possible, of reducing the frequency of such actions, of rendering defense—or compromise, if that be indicated—more equitable and effective, and of procuring relief and redress in actions inaugurated and carried on without probable cause, (4) to study and advise generally with respect to legal and legislative matters of concern to the science of medicine and to the medical profession

The problems which will come up will be many and intricate and their satisfactory solution will depend on proper organization and operation of the Bureau Success will depend also on the whole-hearted support and cooperation of the profession which is earnestly requested in this effort of the Association to benefit its members and the general public

Medical News

(PHYSICIANS WILL CONFER A FAVOR BY SENDING FOR THIS DEPARTMENT ITEMS OF NEWS OF MORE OR LESS GENERAL INTEREST SUCH AS RELATE TO SOCIETY ACTIVITIES NEW HOSPITALS, EDUCATION PUBLIC HEALTH ETC)

CALIFORNIA

Revocation of Licenses—It is reported that the state board of medical examiners has revoked the license of Frederick Nathaniel Staples, on a charge that he was guilty of having been party to a criminal abortion, resulting in death——It is also reported that the board revoked the license of Charles E Marsh, a naturopath, on a similar charge

Arrest of Medical Impostor—It is reported that a person using, at different time the names Leslie Hollen Leslie Powell, J Mitchell Palmer and Thomas Holland was arrested recently in Los Angeles, on a charge of passing bogus checks and of having forged names of reputable physicians to prescriptions for narcotics He asserted that he had practiced medicine in New York and Philadelphia He claimed also to have been a major in the army

CONNECTICUT

Personal—Dr Marvin Z Westervelt, who has recently been in charge of the employee health service of the Winchester Arms Company, New Haven, has been appointed superintendent of the Staten Island Hospital, Tompkinsville

N Y—Dr Thomas F O'Loughlin has been appointed health officer of Vernon to fill out the unexpired term of Dr Wright B Bean, who resigned recently

Yale Medical Alumni Association—At the annual meeting of the association at New Haven, June 19, it was voted to change the name of the organization to "The Association of Yale Alumni in Medicine," and to admit all Yale physicians whether graduates of the Yale Medical School or other departments of the university It was announced that the class of 1922 has agreed to contribute $3,000 to the school in ten annual instalments of $300, the money to be used as loans to worthy students This will be known as the "Loan Scholarship Fund, Class of 1922" The following officers were elected president, Dr Charles E Farr, New York chairman of the executive committee, Dr Herbert K Thoms, New Haven, and secretary-treasurer, Dr Simon B Kleiner, New Haven

DELAWARE

Medical Examiners Appointed—Governor Denney has reappointed Drs Presley S Downs, Dover, Henry W Briggs Wilmington Edwin S Anderson, Dover, and Abram E Frantz, Wilmington, as members of the state board of medical examiners

DISTRICT OF COLUMBIA

Child Health Demonstrations—The Commonwealth Fund will finance a child health program in three typical cities for a period of five years The general qualifications of the first city to be selected are that it shall be from 15,000 to 25 000 in population, with an infant mortality of approximately 100 per thousand live births, or greater Announcement of this action was made, June 29, by Courtenay Dinwiddie, executive secretary of the Child Health Committee for the Supervision of Three Child Health Demonstrations, Washington The program will comprise safeguarding the health of the expectant mother, laying a good health foundation for children in the early sensitive and formative period of their growth, and health supervision and the formation of the essential health habits in schoolchildren The responsibility for carrying out this comprehensive child health program is placed on the American Child Hygiene Association and the Child Health Organization of America A joint committee has been formed that will have charge of all general policies, consisting of Dr Philip Van Ingen and Dr Richard A Bolt of the American Child Hygiene Association, Dr L Emmett Holt and Miss Jean of the Child Health Organization of America Dr Livingston Farrand and Courtenay Dinwiddie of the National Child Health Council, Dr Donald B Armstrong, of the National Health Council, and Mr Barry Smith and Miss Quin of the Commonwealth Fund An office will be opened at 532 Seventeenth Street N W, Washington, and active work will begin at once It was decided by the committee at their first meeting that the first city to be assisted will be selected from the upper half of the Mississippi Valley region Two other cities are to be selected in other sections of the country after work has been well started in the first The work will be so developed as to enlist the cooperation of physicians, public health nurses, school nurses and all other persons and agencies interested in health and child welfare in the communities selected

FLORIDA

License Revoked—The Tampa *Tribune* states that the license of Dr Riley C Hammers, former Tampa physician was revoked at a session of the state medical examiners board, June 13 This is the first time that a physician's license has been revoked by the examining officers of Florida it is stated Dr Hammers has served several terms in prison for rape and violation of the Harrison Narcotic Law

GEORGIA

Atlanta Graduate School of Physicians and Surgeons—The formal opening of the Atlanta Graduate School of Physicians and Surgeons will take place in the fall The general offices of the school are located in Grady Hospital In addition to the city hospital, practically every private sanatorium in Atlanta will be affiliated with the graduate school Dr William Perrin Nicolson has accepted the office of dean, and Dr Michael Hoke has accepted the position as president of the faculty Dr Garnett W Quillian is vice dean and Dr Frank L Eskridge is proctor for the faculty The executors of the estate of the late Albert Steiner have definitely agreed to erect two new buildings for the Grady Hospital, one to be a modern outdoor clinic building which will be used exclusively by the visiting staff for the care of white patients, and the other to be devoted exclusively to the study, diagnosis and treatment of cancer The first course offered at the graduate school will be one in orthopedic surgery and following that courses in general and abdominal surgery, gynecology and obstetrics internal medicine, eye, ear, nose and throat pediatrics, dermatology, neurology, urology and oral surgery

ILLINOIS

Child Health Clinic—A medical clinic for physical defects and underweight children was held in Bloomington June 20, by Dr George T Palmer, president of the Illinois Tuberculosis Association, and Dr Robert H Hayes, Chicago

Personal—Dr Willis T Zeigler, Canton, has been elected county physician of Fulton County to succeed Dr Jasper M Adams——Dr Nelson A Lowry, Chicago addressed the final meeting of the Peoria City Medical Society June 15, on the subject of "Paravertebral Anesthesia"——Dr Daniel N Eisendrath has returned to Chicago after a two years' stay abroad

Hospital News—A twenty-five room addition will be erected at the Burlington Hospital——Construction work will begin immediately on the Mary Davier Hospital at La Harpe ——Plans are being revised for the South End Hospital building Chicago which will be erected at a cost of $300 000 ——A new $130 000 building will be erected for Memorial Hospital Harvey, Cook County——A new laboratory will be established at the Galesburg Cottage Hospital

Chicago

Physicians Club Elects—At the annual meeting of the Physicians Club, held July 1, the following officers were elected secretary, Dr Frederick C Test, directors for one year Dr Truman W Brophy, Dr A A Goldsmith Dr A A O'Neill, and director for two years, Dr John E Rhodes Dr Arthur M Corwin and Dr Henry T Byford

Rush Alumni Honor Professor Haines—At the annual banquet of the Alumni Association of Rush Medical College, Prof Walter S Haines was presented with a watch in which was engraved a statement recognizing his fifty years' service in medical teaching At the same time the Alumni Association announced the establishment of a Walter S Haines Fund for the college library the subscriptions to be completed within four years, at which time Professor Haines will have completed fifty years' service in Rush

LOUISIANA

Physician Gives Donation to University—Dr Leon L Solomon New Orleans has announced that he will give the University of Louisville the sum of $500 annually for use in the medical research laboratory of the university This fund will be known as the Solomon Fund

Measure to Aid Records—Senator Doussan's bill providing for a fee of 25 cents to be paid to physicians, midwives and other persons required to issue birth and death certificates passed the Senate, June 19 It was stated by Senator Doussan that the payment of the fee would probably encourage negro midwives in the parishes to report births

Maternity Bill Opposed—After prolonged arguments for and against the measure, the Senate Committee of Health and Quarantine, June 21, reported unfavorably on representative Dymond's maternity bill which provides that Louisiana give its assent to the Sheppard-Towner maternity *bill* Senator E H Robert New Orleans, argued in favor of indefinite postponement of the bill and pointed out that the states of New York, Massachusetts, Maryland and Maine had rejected the bill

MAINE

Physician Fined—It is reported that Dr Alexander C. Hagerthy, for many terms mayor of Ellsworth, was tried in the District Court June 13 charged with illegal possession of twenty cases of whisky Dr Hagerthy was fined $500 and costs and about $15,000 worth of liquor found in the cellar of his residence was confiscated

Maine Medical Association—At the annual meeting of the association held at Portland June 26-28, under the presidency of Dr Addison S Thayer, Portland, the following officers were elected for the ensuing year president, Dr Langdon T Snipe, Bath, president-elect, Dr Charles A

Moulton Hartland, first vice president Dr John W Nichols Farmington, second vice president Dr Walter N Miner, Calais, and secretary-treasurer, Dr Bertram L Bryant Bangor The next meeting will be held at Houlton, June 12-14 1923 Dr Olin West, Chicago, traveling secretary of the American Medical Association, and Dr Channing Frothingham, Boston, gave addresses

MARYLAND

Hess Dispensary Completed—The new medical and orthopedic dispensary in connection with the Hebrew Hospital has been completed and clinics, which will be housed there will be in operation within the next few weeks The dispensary is a gift to the hospital by Morton Samuels and is known as the Hess Dispensary, in memory of Mrs Samuel's parents

Diphtheria Immunization Clinic Opened—The school of hygiene and public health of Johns Hopkins University in cooperation with the department of health of Baltimore city, has opened a diphtheria immunization clinic, which will be conducted during the months of July and August It offers to any physician the privilege of recommending any family in his practice for admission, when immunity produced by toxin-antitoxin can be brought about before the diphtheria season is here

Personal—Dr J H Mason Knox, Jr of Baltimore, has accepted appointment as chief of the state bureau of maternity and child hygiene created at the last session of the legislature under provisions of the Sheppard-Towner Act Dr Knox is now in Europe where he is directing child hygiene work for the American Red Cross with headquarters at Paris He is at present at Riga Esthonia from which place he cabled acceptance to Dr John S Fulton secretary of the state department of health——Dr T Capsar Gilchrist Baltimore sailed on the steamship *La France* for England and will spend the next two months traveling abroad Dr Gilchrist will deliver the annual address before the London Dermatological Society July 13 in London——Dr Richard Follis Baltimore, has sailed for Europe and will spend his time traveling through England and on the continent, returning September 20

MISSOURI

Personal—Dr C H Wallace, St Joseph has been appointed a member of the welfare board by Mayor McIlmich to succeed Dr Daniel Morton, who declined reappointment ——Dr J E Jordan, Columbia, was presented with a gold watch as a token of esteem recently by the Boone County Medical Society Dr Jordan is retiring from practice owing to injuries received in an automobile accident last fall—Dr William P Fischer, Columbia, has been elected secretary of the Boone County Medical Society to succeed Dr Jordan ——Dr J W Boger, Sedalia, has been appointed county health officer of Pettis County—Dr Henry L Wilfner St Louis has resigned from the board of education after nine years of service——Dr Edward S Smith Macon, has been selected one of twenty officers to be sent to Harvard University for a special course in medicine

MONTANA

State Medical Meeting—The annual meeting of the Medical Association of Montana will be held at Great Falls July 12-13, under the presidency of Dr Wyman W Andrus, Miles City Dr Joseph C Bloodgood Baltimore, Dr Ernest M Hammes, St Paul, Dr David S Hillis Chicago, Dr Leonard G Rowntree Rochester, Minn and Dr Dean Lewis Chicago, will be among the visiting physicians who will gives addresses

NEW JERSEY

Medical Society of New Jersey—At the one hundred and fifty-sixth annual session of the society held in Spring Lake June 20-22, under the presidency of Dr Henry G Costill Trenton the following officers were elected for the ensuing year president Dr James Hunter, Jr, Westville vice presidents, Drs Wells P Eagleton, Newark Alexander MacAlister Camden and Archibald Mercer Newark, secretary Dr William J Chandler, South Orange and treasurer, Dr Elias J Marsh, Paterson

Aid for Unwedded Mothers—A conference was held in Trenton recently, under the auspices of the bureau of child hygiene and the state board of health to consider means for extending the work in regard to problems relating to unwedded mothers, including their care and that of their children A plan was proposed to enlist the cooperation of the general public especially the women, so that it may be possible for illegitimate children, of which there are approximately 1,000 a year born in New Jersey, to have a square deal"

NEW YORK

Personal—Dr Haven Emerson has been appointed full-time professor of the department of public health administration at Columbia University, New York, by the board of trustees of the university——Following his retirement from active service at the Harlem Hospital, Dr Irving S Haynes was tendered a complimentary dinner by members of the medical board of the New York Athletic Club, June 8——Dr Alec N Thomson, director of medical activities of the American Social Hygienic Association, New York has been appointed to the staff of the committee on dispensary development of the United Hospital Fund, New York

Camp for Pertussis Patients—The Riverside Convalescent Camp on North Brother Island, for patients suffering from whooping cough, was opened June 26, by the New York City Health Department It will be under the direction of Dr Robert J Wilson, director of hospitals for the department and Dr Thomas Joyce will be in direct charge At the present time, there are about 500 children in the city afflicted with this disease, and very few of the hospitals in the city have provisions for caring for them while they are convalescent In the new camp, there are accommodations for 2 000 children who will be kept there for a period of six weeks or longer without expense to their parents

Change in Compensation Law—The following amendments have been made to the Workmen's Compensation Law, effective July 1 1922

Explanation Matter in *italics* is new matter in parenthesis is old law (to be omitted)

Article 2 Section 13 Treatment and care of injured employees The employer shall promptly provide for an injured employee such medical surgical or other attendance or treatment nurse and hospital service medicine crutches and apparatus *for such period* as the nature of the injury *or the process of recovery may require* (during sixty days after the injury but the commission may where the nature of the injury or the process of recovery requires a longer period of treatment require the same from the employer) If the employer fail to provide the same after request by the injured employee such injured employee may do so at the expense of the employer The employee shall not be entitled to recover any amount expended by him for such treatment or services unless he shall have requested the employer to furnish the same and the employer shall have refused or neglected to do so or unless the nature of the injury required such treatment and services and the employer or his superintendent or foreman having knowledge of such injury shall have neglected to provide the same *nor shall any claim for medical or surgical treatment be valid and enforceable as against such employer unless within twenty days following the first treatment the physician giving such treatment furnish to the employer and the industrial commissioner a report of such injury and treatment on a form prescribed by the industrial commissioner*

New York City

Personal—Dr Harold W Hersey has resigned as head of the New Haven Hospital to take a position on the administrative board of Columbia University and the Presbyterian Hospital——Dr Thomas H Cherry and Dr Julius Auerbach sailed for Europe on the American Liner *Resolute*, June 27 ——Dr and Mrs Russell A Hibbs sailed for Europe on the *Celtic* July 1——Dr and Mrs David Hunter McAlpin Dr Frederic E Sondern and Dr Samuel S Gant sailed for Europe on the *Homeric* of the White Star Line, July 1—— Health Commissioner Dr Royal S Copeland sailed for Europe on the *France* June 28 in order to obtain first hand information as to health and sanitary conditions abroad His ultimate destination is Poland where he will spend several weeks investigating conditions in the typhus-infected district He is representing the city of New York at the International Congress for the Protection of Mothers and Infants held in Paris July 6 to 8

Hospital News—The eleven-story addition to the Broad Street Hospital was formally opened, June 19 The institution has accommodations for 100 patients The Grand Lodge of the State of New York finances the Masonic floor, the seventh floor will be known as the Roosevelt Memorial floor for children and will be financed by William Hamlin Childs Mrs James Barber will finance another floor, which will be known as the Nora Nickle Barber Maternity floor For the maintenance of the hospital every business firm south of Chambers Street will be asked to contribute a stated sum annually Every firm may protect its employees by paying $1 a year per person with a minimum of $25 During the past five weeks, 115 firms, with a total of 15 000 employees have taken out this form of health insurance——The Montefiore Hospital for Chronic Diseases has purchased a plot 50 by 100 feet adjacent to its home on Gun Hill Road

and also acquired a lot, 125 by 100 feet, on the east side of Steuben Avenue. The hospital recently bought five lots adjoining the latter purchase on the north.

OHIO

Hospital News.—A tuberculosis sanatorium will be erected at Cleveland exclusively for Jewish people.——Plans to issue bonds for $300,000 for a new building at the Flower Hospital, Toledo, have been made.

Physician's License Restored.—The license of Dr. Alfonza Aratus of Cincinnati, which was revoked in 1909 in Ohio and in 1917 in Kentucky, was restored in the state of Ohio in December, 1917, according to a recent report.

Ohio Licenses Revoked.—The license of W. H. Blanck, Cleveland, is reported to have been revoked on the ground that he is now serving a term in the penitentiary for committing an alleged abortion.——The certificate of J. D. Clyne of Cleveland, alleged abortionist, has likewise been revoked.——The certificate of M. Lowenthal, Cleveland, was revoked on the ground that he was convicted of violation of the Harrison Narcotic Law, as a result of which he was sentenced to four years in the penitentiary and fined $2,000.——The certificate of Katherine Kolling, a midwife, Cleveland, was revoked on the ground that she was serving a term in the penitentiary for alleged abortion.——The certificate of S. E. Zeigler of Akron was revoked on the ground that he had been convicted of violating the Harrison Narcotic Law.

Personal.—Dr. John M. Withrow, Cincinnati, received the honorary degree of doctor of laws at the eighty-third annual commencement of Miami University, in recognition of his work in the interests of the public schools in Cincinnati.——Dr. Felix T. Revailles of the Ohio Hospital for Epileptics, Gallipolis, was knocked down and badly beaten, and four patients were stabbed, while trying to subdue a patient who ran amuck recently.——Dr. H. H. Goddard has resigned as director of the state bureau of juvenile research, and Dr. Edmund M. Baehr, psychiatrist for the department of welfare, has succeeded him. Dr. Goddard will become professor of abnormal psychology at Ohio State University in the fall.——Dr. Carl L. Mueller, health commissioner of Wapakoneta, has been elected secretary of the newly organized Auglaize County Public Health League.——Dr. Frank D. Phinney, Cincinnati, has been made a citizen of the United States. Dr. Phinney immigrated from Canada in 1895.——Dr. Edgar J. Curtiss has been appointed physician for the Allen County Children's Home, to succeed Dr. Jonathan B. Vail, resigned.

OKLAHOMA

University of Oklahoma.—During the year 1921, improvements were made at the University of Oklahoma Medical School, Norman, in the way of remodeling, at an expense of $6,000,000. An additional building was provided for the University Hospital at a cost of $75,000, which increased the capacity from 176 to 276 beds, and a nurses' home was erected at a cost of $60,000. The legislature provided an appropriation of $20,000 for radium. As the hospital is directly under the management of the school of medicine, all of these improvements add to the facilities of the school.

OREGON

Pacific Northwest Urological Association.—This organization was recently formed, composed of specialists in urology, with Dr. Albert E. MacKay, Portland, president, Dr. Eric W. Boak, Victoria, B. C., vice president, and Dr. William J. Pennock, Spokane, secretary-treasurer.

PENNSYLVANIA

Hospital News.—Reading Hospital has sold its building for $600,000 and a site for $100,000 and $1,000,000 is now available for a new building.——An addition to Mount Sinai Hospital, Philadelphia, doubling the capacity of the institution, was formally opened and dedicated, June 25. Judge Patterson delivered the dedicatory address. A feature of the new addition is an animal experimentation laboratory which is maintained by the Federation of Jewish Charities, for scientific research and investigation in connection with its social welfare organizations. The new houses adjoining the hospital will be purchased in the near future and the hospital will occupy the entire block.

Medical Extension Service.—Establishment in the near future of a state-wide medical extension service as a result of the efforts of leaders in the medical profession, was forecast June 14, at a meeting of the Philadelphia County Medical Society. Dr. George H. Meeker, dean of the graduate medical school of the University of Pennsylvania, is one of the principal sponsors of the plan, according to Dr. James M. Anders, who referred to its possibilities and value in a paper on "Some Deficiencies of Modern Therapeutics." This will enable physicians who, busy with their practices, have not kept in touch with the latest achievements by fellow members of their profession or with discoveries and improved methods in its every branch, to be kept constantly informed through the extension service, which will have branches in practically every hospital of the commonwealth.

Philadelphia

Medical Agent Charged with Graft.—It is reported that after county detectives had listened through a dictaphone for several hours, while Dr. Louis Saltzmann, an agent of the state bureau of medical licensure, bargained with an official of the County Chiropractors Association, he was arrested, June 10. The Council for the Philadelphia County Chiropractors Association complained to the district attorney that Dr. Saltzmann was trying to extort money from the chiropractors by promising not to prosecute them for violation of the medical practice laws. The chiropractors declared that the association has paid Saltzmann $150 a month for several months not to prosecute them. The bureau of medical licensure stated that he had been employed by them as a detective to gather evidence against persons believed to be practicing without a license.

RHODE ISLAND

Rhode Island Medical Society.—At the annual meeting of the society held in Providence June 1, under the presidency of Dr. George S. Mathews, Providence, the following officers were elected for the ensuing year: president, Dr. Frank E. Peckham, Providence; first vice president, Dr. Arthur T. Jones, Providence; second vice president, Dr. William F. Barry, Woonsocket; treasurer, Dr. Winthrop A. Risk, Providence; and secretary, Dr. James W. Leech, Providence.

SOUTH CAROLINA

Public Health Lectures.—In the monthly report of County Health Commissioner Chimene, it is stated that fifteen public health lectures were given during the month of May in Greenville with an estimated number of 1,045 persons in attendance. Three hundred and fifty children were examined, and motion pictures were exhibited at the mills on the subject of prevention of venereal disease.

Personal.—Dr. J. Baxter Haynes, Spartanburg, and Dr. J. S. Matthews, Denmark, have been appointed members of the state board of medical examiners.——Dr. Washington P. Timmerman has been elected president of the Batesburg Board of Trade and of the newly organized Batesburg Medical Society.——Dr. Charles W. Kollock was elected president of the Charleston Tuberculosis Association recently.

TENNESSEE

Orthopedic Clinic.—A new department of the health center of Knoxville was opened June 15, for the treatment of orthopedic cases. Any person in the city suffering from a disease or deformity which may be relieved by orthopedic treatment, and who is unable to pay for the treatment, may secure remedial treatment at the health center.

TEXAS

Hospital News.—The Spohn Hospital of Corpus Christi, which was destroyed by a storm in 1919, has completed its fund for rebuilding on a large and modern plan. Meanwhile, the hospital continues work in a building, with its regular corps of Catholic sisters.——The Ranger City and County Hospital, Ranger, is under construction and will be completed about October of this year. The institution will have a forty-two bed capacity and will be of fireproof construction.

UTAH

New Appointments.—Dr. Clarence C. Jensen, state superintendent of public instruction, Riverton, has been appointed state director of health education to succeed Dr. Ephraim G. Gowans, Salt Lake City, who resigned recently.——Dr. Douglas L. Gamette, Salt Lake City, has been appointed house surgeon at St. Mary's Free Hospital for Children, New York City.

WISCONSIN

University of Wisconsin—Appointment of a committee of the regents and faculty of the University of Wisconsin to consider problems growing out of the proposed construction of the $1,350,000 Wisconsin General Hospital in connection with a four-year medical course of the university has been made This committee will investigate and report to the governor on questions which he wishes answered before authorizing construction

Triple Ownership Plan for Sanatorium.—At a meeting of the tri county sanatorium committee, representing delegates from Fond du Lac Winnebago and Waushara counties, final details of the triple ownership plan for Sunny View Sanatorium, near Oshkosh were agreed on Winnebago is erecting a Hick Memorial Nurses Home near Sunny View and the county has agreed to permit the nurses of the Sunny View Sanatorium to use the nurses' home

CANADA

Hospital News—Plans have been requested for the establishment of a sanatorium, in Ontario, to be erected at a cost of $1,000,000 for the treatment of tuberculous members of the Brotherhood of Railway Trainmen——At a recent meeting of the Kiwanis Club, in Quebec, two huts were presented to Laval Hospital for the use of tuberculous children during the summer months Premier Taschereau accepted the huts on behalf of the hospital

PHILIPPINE ISLANDS

Philippine Islands Medical Association—At the annual meeting of the association held in Manila under the presidency of Dr Baldomero Roxas y Luz, the following officers were elected for the ensuing year president, Dr Harry H Stemmetz, first vice president, Dr Aristeo R Ubaldo, second vice president Dr Daniel de la Paz councilor for five years, Dr Vicente de Jesus De Zabala, and secretary-treasurer, Dr Isabelo Concepcion

GENERAL

Russians Honor American—A delegation of sixty, representing the various Russian organizations in Greater New York met the body of Harold F Blandy, the first American relief worker to die in Russia from typhus, when it arrived on the *Poloma* June 23, from Libau

American Psychiatric Association—At the annual meeting of the association held in Quebec Canada June 6-9 the following officers were elected for the ensuing year president Dr Harry W Mitchell, Warren Pa , vice president, Dr Thomas W Salmon New York and secretary treasurer, Dr Clarence Floyd Haviland, Albany, N Y

American Neurological Association—The American Neurological Association at the annual meeting at Washington D C, elected Dr Harvey Cushing Boston president of the society Other officers elected were Drs Herman H Hoppe Cincinnati, and Charles S Potts, Philadelphia, vice presidents, and Dr Frederick Tilney New York secretary-treasurer

American Urological Association—At the annual meeting of the association held at Atlantic City May 26 28 the following officers were elected for the ensuing year president, Dr Henry L Sanford, Cleveland vice president, Dr James A Gardner Buffalo secretary, Dr Homer G Hamer Indianapolis and treasurer, Dr James B Cross Buffalo The next annual meeting will be held at Rochester, Minn

Report of Infant Mortality—The American Child Hygiene Association has published its third annual report of infant mortality in cities of over 10 000 population in Continental United States Data were sought only from cities in the death registration area and of these, 573, covering 94 4 per cent of the population, are included in the report A remarkable reduction in infant mortality throughout the country is shown In cities of over 250 000 population the infant mortality rate dropped from 89 0 in 1920 to 75 3 in 1921 The rate in cities with a population between 10 000 and 25 000 dropped from 93 8 in 1920 to 82 3 in 1921 The rate for all cities in the area dropped from 91 5 to 77 9 Of the cities included in the report having more than 250 000 people Portland Ore San Francisco and Seattle had the lowest infant mortality rate Pittsburgh, Kansas City, Mo, and Buffalo had the highest rates

National Health Council Issues Report.—The U S Bureau of Animal Industry is concerned chiefly with the welfare of animals Much of the work of this bureau however relates to human health In order to present a brief outline of the activities of the bureau, the National Health Council has issued a mimeographed report setting forth the legal authority, history and development of the bureau, its organization, personnel and appropriations, and its cooperation with other agencies It is the eighth in a series concerning the health activities of the United States government which has been issued by the council It is planned in the near future to combine all of these reports in a single printed pamphlet thus offering for the first time correlated and accurate information concerning the public health work of the United States government Copies of the report on the Bureau of Animal Industry, or of any of the other reports, may be obtained without charge from the Washington office of the council, Seventeenth and D streets N W, Washington, D C

Nursing Education Program—A program of nursing education that seems to have the unanimous support of the physicians, nurses and public has been effected recently For three years, a committee has been studying the problem, which began with the question of the proper training of public health nurses The personnel of this committee consisted of Dr C E Winslow professor of public health, Yale University Medical School, New Haven, Dr Welch, Johns Hopkins University Baltimore, Dr Edsall of Harvard, Boston, President Farrand of Cornell, Ithaca, Commissioner Biggs, Dr L Emmett Holt and Dr Conner New York and others Unanimous recommendations urge three grades of nursing service (1) the trained registered nurse for the care of the acutely ill the present training course to be reduced 20 per cent in length (that is, to two years and four months), but with such improvement as not to lower present standards (2) the public health nurse the supervisory nurse and the teacher in schools of nursing, who shall receive specialized graduate training beyond the standard course, and (3) the subsidiary nursing worker, who shall be trained in a course of eight or nine months and be licensed as a nursing aid' or nursing attendant' for the care of minor and chronic illness and convalescence Thus, it is proposed to maintain the present R N standards, and at the same time to give further protection to the public through standardizing the subsidiary type of nurses under a description that will not be distasteful

Bequests and Donations—The following bequests and donations have recently been announced

Children s Free Hospital Fund Wisconsin $128 962 as final payment of the $150 000 pledge by the Ferdinand Schleisinger estate

Youngstown Hospital Association Youngstown Ohio $100 000 for a maternity ward to be known as the Grace Todd Arrel Maternity Ward Trust Fund by the will of Mrs Grace Todd Arrel

Madison Wis for the establishment of a hospital to be conducted by the Norwegian Lutheran Church of America $50 000 on condition that $100 000 is raised in six years by the church to be donated by Torger G Thompson

Methodist Episcopal Hospital Brooklyn and the General Hospital Society of Connecticut $25 000 each by the will of William P Armstrong

Flushing Hospital Flushing L. I $25 000 by the will of Mrs Angeline M Booth

Grinnell Community Hospital Association Grinnell Iowa about $25 000 on the death of her sister by the will of Sophronia G Turner

Woman s Medical College of Pennsylvania Philadelphia $21 000 the income to be used for scholarship purposes by the will of Dr Emma Culbertson of Boston

Jewish Convalescent Home Torresdale Pa $15 000 an initial donation of $10 000 by Joseph B Fursman to build a separate wing for cardiac cases and $5 000 that was contributed at the annual meeting of the directors

Fifth Avenue Broad Street and the Lenox Hill hospitals New York and the Sisters of the Poor of St Francis and St Vincent s hospitals each $5 000 by the will of Nicholas Rath

Barton Dispensary Philadelphia approximately $1 000 in pledges by the alumnae of the Woman s Medical College of Pennsylvania at their annual meeting

Hollywood (Calif) Hospital Association $500 anonymously

Sisters of St Mary Baraboo Wis property for a hospital by Mrs Della Ringling of Baraboo

For the benefit of humanity the residue of her estate and forty acres of her farm near Warrenton Ore for a public park in memory of her parents on her death by Dr B A Owens Adair

Department of Labor—Secretary of Labor Davis in a communication to Surgeon General Cumming of the U S Public Health Service requests full information as to the legislation necessary to secure a thorough physical examination of every alien who is admitted to the United States through the immigration ports Secretary Davis also announced his intention of recommending to Congress the enactment of such legislation at the earliest possible moment His communication reads in part as follows

The protection of the health of American citizens against disease carried by incoming aliens is of the utmost importance and it seems to me should be thorough at every port I note in your recent statement that Ellis Island N Y and Angel I land Calif are the only immigration stations that have satisfactory facilities for a thorough medical examination Surely Seattle and Boston are important ports where many aliens enter and thes should be medically in the same

class with Ellis Island and Angel Island I am assuming that all ports have equipment which will make thorough examinations possible but that the want of equipment at some of the smaller ports merely requires a longer time to complete an examination and that additional equipment at the larger ports facilitates examination In the final analysis loathsome contagious diseases are as dangerous to American citizens when coming through a small port as when coming through a large port It is barely possible that those afflicted with diseases knowing that the examinations at the smaller ports are not so thorough seek the smaller ports for entrance The subject of examination of seamen seeking shore leave I think requires immediate and thorough attention The privilege of shore leave applies to all seamen including even the races which are barred as immigrants and the zones from which the immigrants may not come Seamen in the very nature of things touch some time or other all the ports of the world and thus are more likely to be carriers of disease than are immigrants If there is no provision in the law for thorough examination of seamen who seek shore leave the provision should be made therefor Will you be good enough to give me a full and detailed statement of what is necessary by way of either legislation or appropriation so far as you know in order to secure a thorough examination medically of every alien who enters the United States at any port anywhere? Also kindly indicate to me if you will the scope of legislation so far as your own bureau is concerned for extending the service so that I may know what legislation should be provided in connection with this department Also kindly let me know what provision by way of appropriation for the extension of the service is made in connection with your service so that I may know what recommendations to make for extending the service so far as this department is concerned I should appreciate it if you would give me this report as soon as possible so that I may have it when preparing my report to the President and to Congress for the fiscal year ending June 30 1922

FOREIGN

Postgraduate Work in Vienna—A cablegram just received from Dr Kettelkamp, Secretary of the American Medical Association of Vienna, states 'The unhappy conditions set forth in our letter of March 14 have been adjusted Postgraduate work in Vienna is on pre-war basis"

Bust Presented to Thibierge—The retirement of Dr G Thibierge from his dermatologic service at the Hopital Saint-Louis at Paris was the occasion of the presentation of a bronze portrait bust, and tribute from numerous speakers who lauded not only his scientific work but his leadership in organization, and skill in teaching

Cancer Research Committee—The minister of hygiene in France has organized a special commission to coordinate the efforts and research in regard to the etiology, clinical study, treatment and prophylaxis of cancer Dr E Roux of the Pasteur Institute is the honorary president of the commission and Prof Quenu is the acting president The commission includes a large number of clinicians and workers in these lines

University News—At the annual commencement of the Mukden Medical College, Dr Dugald Christie, principal of the university, gave the opening address It was announced that in 1924, through the generosity of Sir Joseph Maclay former British shipping controller, the Mukden Medical College will be open to women students — The Rev Dr Webster addressed the students and opened a new outpatient department of the Mukden Hospital, which is attached to the college of medicine

Infant Welfare Conference—The week of July 3-8 will be known as Baby Week in London The object is to further the child-adoption movement for Great Britain Until the present time, legal adoption of children in that country could not be carried out and the new propaganda aims at enactment of laws to legalize such adoptions This may result in a plan for adoption of English orphan children in American families Dr Henry Dwight Chapin of New York who sailed for England, June 21, will give an address at the conference entitled "An Alternative to the Institutional Rearing of Children"

Kuling Medical Association—The summer activities of the Kuling (China) Medical Association include, Good Health Week, July 17-22, a course for educational workers and mothers, in which they will take up school inspections simple physical examinations and corrective hygiene, a course in physical training for girls, scientific health lectures every evening during Good Health Week, by Prof C H Robertson, a sanitary survey of Kuling under the direction of Dr R M Atwater, a course in physical training for Chinese at Lily Valley in August, by Dr Gray of the Y M C A, Shanghai, and the annual banquet of the association, August 1

Knighthoods for the Medical Profession—The list of honors conferred in June, on the occasion of the king of England's birthday, contains the names of several members of the medical profession Sir Berkeley Moynihan, who has founded the most outstanding school of surgery in the country, received a baronetcy Knighthoods were allotted to Dr H Kerr Anderson master of Gonville and Caius College, Cambridge Prof W M Bayliss, professor of physiology, University College, London, Dr John Macpherson, professor of psychiatry, University of Sydney, Australia, Dr Douglas Rice Oxley, mayor of Kensington, London and Dr David Maurice Serjeant In the Order of the Bath, knighthoods were given to Sir Robert Hill, director general of the medical department of the Royal Navy, Major General Klenkinsop, and Mr Richard R Cruise, surgeon-oculist to the king, Major A W Lynsdale professor of materia medica, Madras Medical College, becomes Companion of the Imperial Service Order

Personal—Prof E Schmiegelow of Copenhagen has been elected an honorary member of the Vienna Laryngologic Society——The *Ugeskrift for Læger* relates that Dr T Madsen of Copenhagen has been given the Polish decoration Polonia Restituta——A banquet was tendered recently to Dr G Marañon of Madrid to celebrate his election to the Academia de Medicina His address on taking his chair was on the present status of the theory of internal secretions——The Spanish Gynecologic Society recently held a special session in honor of Dr Cospedal who is retiring from charge of the Princesa Hospital having reached the age limit——The *Medicina Ibera* relates that Dr L Recasens was the guest at a banquet given in honor of his successful competition for a post in the Beneficencia Municipal——Prof Martinez Vargas, dean of the Barcelona medical faculty, has been appointed senator——The completion of forty years of university teaching by Prof E Maraghano is to be celebrated by the foundation of a medical library at the University of Genoa to bear his name

Deaths in Other Countries

Dr **Edmund Fallows Lawson**, C M S, Hospital Funing, Fukien, South China and Dr Marcus MacKenzie, both medical missionaries from England, contracted pneumonia plague while attending the sick and died in Foochow, recently——Dr **Gordon Ley**, London, gynecologist, Charing Cross Hospital in an aeroplane accident in the English Channel, June 3——Dr **G Martin**, a prominent ophthalmologist of Bordeaux——Dr **C E Mariani**, of Turin editor of the *Archivio di Antropologia Criminale* and director of a private sanatorium He has published a number of works on criminal psychology, teratology, psychic epilepsy, etc——Dr **F Boschetti**, professor of clinical medicine at the University of Modena——Dr **J W Cardoso** of Rio de Janeiro

Government Services

Additional Grounds for Walter Reed Hospital

President Harding through the director of the budget, has recommended to Congress that the sum of $440 000 be appropriated for the acquisition of additional land for the Walter Reed General Hospital, Washington, D C The sum of $350 000 has already been appropriated by the legislative branch, but it has been found that this is insufficient to carry out the plans for securing the property in the vicinity of the institution

Nursing Service for Disabled Veterans

Before taking its summer recess the House of Representatives passed the pending bill providing the maximum amount to be paid disabled ex-service men requiring the constant assistance of a nurse or attendant The sum fixed was $50 a month Heretofore, disabled ex-service men were allowed $20 a month for a nurse or attendant The law applies specifically to disabled veterans who are totally blind or suffering with mental diseases that do not confine them to an asylum

Vocational School for Neuropsychiatric Cases

A resident vocational school for neuropsychiatric cases has been established by the U S Veterans' Bureau at Chick Springs, S C The institution will provide for treatment of 250 disabled ex-service men, already assigned there A systematic course of instruction such as is feasible for neuropsychiatric patients has been established The vocational school and hospital consists of a new building fully equipped with machinery, by which students will learn various trades, with additional facilities for medical treatment A corps of experienced teachers has been engaged by the Veterans Bureau to supervise the training while physicians and nurses will look after the physical welfare of the ex-service men

Deanglicization of the Indian Medical Service

The Indian Medical Service which used in its upper ranks to be almost entirely recruited from Great Britain is rapidly losing its British element It is true that Indians were always eligible but the very difficult competitive examination was held in London and the Indian medical schools had not reached a level capable of turning out competitors The Indians who competed were therefore the few who could be educated in England, and they furnished only a small minority of the service There was a "subordinate medical service" recruited entirely from India and manned by men termed the "assistant surgeons," whose training was below the European standard, and they permanently held a subordinate rank With the recent granting of powers of self-government to India and the improvement of its medical schools natives have entered the medical service in greatly increased numbers The result is that a newly appointed British officer is faced with the possibility of having to work under seniors who may be natives This is objectionable to the ordinary Britisher, and the result is that there is greater and greater difficulty in recruiting the service from British sources At one time the Indian Medical Service was considered a splendid field for able and ambitious young physicians The pay was higher than that of the medical service of the British army and, in addition, valuable civil medical appointments in India were a perquisite of the service for there were no other physicians available The result was that the service reached a high level and numbered many investigators who shed luster on British medicine With the exception of Manson all the pioneers of tropical medicine belonged to its ranks Now the difficulty of recruiting is so great that the competitive examination has been dropped, and even British physicians cannot be induced to enter Recruiting in England is at a standstill If the native physicians who have taken the place of British maintain the same high standard of efficiency nothing can be said against the change as regards the military part of their work for that is virtually confined to native troops But there is the difficulty that the European population of India is dependent on the service for medical attendance, and objects to be handed over entirely to natives however skilful they may be It was recently stated in the House of Commons that in the country districts of Bengal there are only five European physicians and that of twenty-four country districts of Madras there is a European physician in only seven The result will be that the Indian Civil Service also cannot be recruited in England for the Englishmen cannot be expected to take their wives up country to places where they cannot call in an English physician

Retirement of Dr Head

A complimentary dinner was recently given to Dr Henry Head, F R S on his retirement in recognition of his services as editor of *Brain* for seventeen years The chair was taken by Sir Charles Sherrington F R.S professor of physiology at the University of Oxford and president of the Royal Society, whose outstanding contributions to neurology are so well known Proposing the health of Dr Head he said that under his direction the influence of *Brain* had been increased and extended forming a bond between the neurologists in these islands and those across the channel and beyond the Atlantic Every worker in neurology knew that he could get a sympathetic hearing and an opportunity from Dr Head He had consistently upheld the scientific method in neurology and in his own work He had his reward in the position *Brain* had obtained as a worthy representative of British science

Sir David Ferrier, one of the founders and original editors of *Brain* then sketched its history In 1877 those interested in neurology felt the need of a special journal The reports of the West Riding Asylum the first school of neurology in this country founded by Sir James Crichton-Browne in 1871 came to an end in 1876 In that year, *Mind* was started by Prof Croom Robertson but it was concerned mainly with pure psychology A committee consisting of Crichton-Browne Bucknill Hughlings Jackson and himself resolved to establish a journal devoted to the anatomy physiology and pathology of the nervous system The title Brain was selected and the first number was issued in April, 1875 It was edited in alternate years by Crichton-Browne and Ferrier for five years Then, Dr de Watteville became acting editor He was followed by Percy Smith, and, in 1905 Dr Head became editor The value of the journal had been greatly enhanced by his epoch making researches

Dr Head in responding, described the early financial struggles of the journal, speaking of the constant deficit which had to be defrayed out of the editorial pocket By rigid economy a condition of financial solvency was at last attained During the war difficulty again arose In the early days Dr Head read Hughlings Jackson's papers on aphasia and was so struck by their importance to science that he reissued them as a double number Congratulatory letters came from all parts of the world, and Von Monakow not only translated them into French but devoted a large issue of the *Schweizer Archiv* to a critical consideration of Jackson's views, which were entirely unknown on the continent Then Sherrington's classic paper on postural activity of muscle and nerve was published Though the issue was sometimes delayed, the journal appeared every year during the war But the colossal rise in the price of paper and in wages again caused a deficit By drastic measures financial solvency was again attained *Brain* had become an international organ of neurology and was universally considered as representative of the serious side of English work English neurology had influenced foreign thought because it had brought something distinctive It had been characterized by two features—dependence on clinical observations and consistency in looking at pathologic facts from the physiologic point of view This began in 1859, when that adventurous genius Brown-Sequard came to England Hughlings Jackson was profoundly influenced by him The next most serious influence on English neurology was the publication by their chairman of the Integrative Action of the Nervous System" which reinforced the tendency always present to regard pathologic facts from a physiologic standpoint, a principle still incompletely assimilated abroad

In closing Dr Head spoke of his pleasure in leaving the journal in the competent hands of his successor, Dr Gordon Holmes

A "Rat Barrack"

A correspondent of the *British Medical Journal* has unearthed the following ingenious method of dealing with rats which he found in Hall's book Ireland, published in 1841

Mr Russell has a rat barrack' on his premises It is about 12 feet long 6 feet broad and 4 feet high with a coping stone on the top that projects a couple of feet inside the wall The inside of the wall is full of holes that just admit a rat's body leaving the tail outside The whole is covered with old boards There are two passages for them to come out into the yard where they are fed and never disturbed The consequence is they never go into his store where the bacon is Once every three months he closes the holes that communicate with the yard He uncovers the walls and the rats all run into the holes Their tails are hanging out. A man goes in takes them one by one by the tails and throws them into a barrel where they are all destroyed to leave room for a fresh supply

The Influenza Epidemic

The quarterly return of the registrar-general shows the severity of the influenza epidemic of the early months of the year Influenza was a primary or secondary cause of death in no fewer than 16,888 cases in England and Wales in the first quarter of 1922, and accounted for 10 2 per cent of the total deaths Moreover, the total deaths were 36,204 more than in the first quarter of 1921 This is usual when an epidemic is prevalent When persons suffering from chronic disease are stricken in the epidemic, cause of death is not given as influenza A remarkable fact is that during the epidemic more women than men died from the disease

PARIS

(From Our Regular Correspondent)

June 9, 1922

De Lapersonne's Mission in America

At a recent session of the Academy of Medicine, Dr F de Lapersonne, professor of clinical ophthalmology of the Paris Faculty of Medicine, presented a report concerning his mission as representative of the academy at the international congress of ophthalmology, held in Washington, April 25-28 Our friends in the great American republic," said de Lapersonne, "made elaborate preparations for the congress, as usual, and its management was perfect" After a review of the principal work of the congress, de Lapersonne spoke of various hospitals and universities that he visited during his short stay in the United States By coming in contact with American colleagues, he was able to observe the important scientific work which is being undertaken, and which is made possible by the extensive means at the disposal of investigators in the United States He stated that it is impossible to imagine, in France, the unlimited resources available for study and the development of private initiative "With their tenacity of purpose and their practical minds," said de Lapersonne, 'American scientists desire to become in medicine, as in other provinces, the first nation of the world" De Lapersonne believes that the results they obtain so rapidly fully justify this ambition American professors expressed the desire to cooperate more closely with their French colleagues through the exchange of scientific works, the reciprocal publication of articles in medical journals of both countries, and the exchange of professors and students The principal obstacle to this is the fact that few Americans speak French and that, in turn, few Frenchmen speak English De Lapersonne believes that it is important for French children to learn English "so that they may benefit by the ever-increasing amount of interesting work coming from Anglo-Saxon races"

Edema of Larynx in Mumps

In a previous letter, I mentioned the occurrence of appendicular manifestations with mumps (THE JOURNAL, May 6, 1922, p 1401) Edema of the larynx is another complication in mumps which seems scarcely to have attracted attention in the past Textbooks and practical treatises on laryngoscopy do not make mention of it, but this complication appears to be more frequent than we think, as is shown by a communication presented by Drs L Reverchon and G Worms to the Societe parisienne de laryngologie During six years in the otorhinolaryngology service of the military hospital of Val-de-Grace, Reverchon and Worms observed three cases of edema of the larynx in mumps The evolution of their two first cases was very simple, and the edema could have been considered as an ordinary clinical curiosity, interesting only on account of its infrequency But a third case, with fatal outcome in less than five hours after admittance to the hospital, and seven or eight days after subsidence of the mumps, demonstrated that this complication can have a serious prognosis notwithstanding the usual benign course of mumps The seat of the edema was the same in the three cases the posterior region of the vestibule, the aryepiglottic muscle This infiltration of the submucous connective tissue was unilateral in the first case and bilateral in the two other cases The three cases of mumps were of submaxillary type, isolated in the first case, and with parotid mumps in the second case Tracheotomy was not performed at once in the third case, because the patient did not present any signs of asphyxia, there was no distress or cyanosis, but he was pale and drowsy On the other hand, laryngoscopic examination revealed that the edema did not reach the epiglottis, and the throat appeared to be sufficiently permeable The slight dyspnea was not accompanied by laborious breathing, and the immobility of the posterior commissure during inspiration, with slight intermittent roaring, recalled bilateral paralysis of the dilators, which, as a rule, does not require immediate tracheotomy This occurrence has demonstrated that the posterior edema, by blocking the arytenoids, presents serious consequences even when the dimension of the glottis is not particularly reduced

During the discussion that followed the communication, Lubet-Barbon remarked that pallor and livid discoloration of the teguments are the main symptoms of nonacute edema of the larynx He has seen crises of asphyxia suddenly complicating this apparently mild condition, and ending with death after two or three days of slight dyspnea On the other hand, these patients may also succumb from syncope rather than from suffocation He has witnessed deaths even after tracheotomy In such cases, then death is due to compression of the pneumogastric nerve or one of its branches

Morbid Disturbances Due to the Handling of Celluloid

The number of occupational diseases is constantly increasing, and Dr F Heim, professor of industrial hygiene of the Conservatoire National des Arts et Metiers, has directed attention to an interesting observation With the collaboration of Drs E Agasse-Lafont and A Feil, he examined, from a clinical and hematologic standpoint, women employed in making small portable battery boxes of celluloid Their ages ranged from 17 to 53, and they have been working with celluloid from one to five years They employ two substances the celluloid powder, containing camphor, is very inflammable and its odor is disagreeable to any one entering the factory, the other is a sort of glue containing a mixture of equal parts of amyl acetate and acetone Their inquiry on morbid manifestations attributed to celluloid intoxication revealed one transitory clinical sign, headache, and a persistent and frequent hematologic symptom, eosinophilia This cause of toxic eosinophilia is important, and Agasse-Lafont and Heim had already reported it after an inquiry concerning the condition of workmen pasting and perforating films in a motion picture studio It resembles somewhat benzene eosinophilia Although it has not the pathognomonic value of granular degeneration of erythrocytes in chronic lead poisoning, this eosinophilia is interesting because it gives an almost indubitable proof of intoxication or, at least, of a reaction to saturation of the organism by fumes of acetone and of amyl acetate On the other hand, the lack of knowledge of this cause of eosinophilia might entail errors in diagnosis, as when a workman handling celluloid is clinically suspected of intestinal parasites or hydatid cyst, as the diagnosis of these affections is often based on the finding of eosinophilia

War Losses

Up to Sept 1, 1921, the pension office had received 2,500,000 claims for pensions or allowances of which 1,712 000 were granted being thus distributed 830,000 among the incapacitated, 447,000 among widows and orphans, and 413,000 among

parents Fifty-nine thousand of the incapacitated were totally invalided, and 60,000 suffered disability amounting to from 80 to 95 per cent The 456,125 pensions granted up to April, 30, 1920, were thus distributed

Percentage of Disability	Final Pensions	Temporary Pensions
10	2 059	56 665
20	3 064	92 390
30	1 120	78 088
40	455	50 013
50	346	38 675
60	14 915	24 465
65	41 553	
80	40 329	6 689
100	5,104	5 645

Following are the statistics of the war wounded From 1914 to 1916 wounded and sick (front and rear lines) 1914, 776,274, 1915, 1,326,911, 1916 677 891, sick 1915 1,117,930, 1916, 899,310 From 1916 to 1919, at the front wounded 1917 269,853, 1918, 212 915, 1919, 23,622, sick 1917 360,911, 1918 321,706, 1919, 87,244 Rear lines wounded, 1917, 338 907, 1918, 610,987, 1919, 46,201, sick 1917, 769 896 1918, 940 452, 1919, 208,380 For Algeria and Tunis wounded 1914 22,015 (including the sick), 1915 8 055, 1916 18,099, 1917 13 696 1918, 12 496, 1919, 2 821 sick 1915, 15 683, 1916 54 005, 1917, 44,835, 1918, 55 870, 1919, 12 946 Summing up these figures we have wounded, 3 594 889, sick, 4 988 213 It may be interesting to compare these figures with those concerning men sent back from the front to the interior of the country 1914, 490,000, 1915, 1 019,000, 1916 551 000, 1917, 375 000, 1918, 675,000

Medical Tours to Water and Health Resorts

Under the direction of Dr Paul Carnot professor of therapeutics in the Paris faculty of medicine, and of Dr F Rathery, associate professor, the sixteenth medical tour to the mineral water and health resorts of France will include the stations of the southwest and those west of the Pyrenees Mountains Arcachon, Biarritz Dax Pau, Cauterets Luchon etc It will take place from August 26 to September 6 of this year Members will meet at Arcachon, August 27 and will disband at Luchon September 6 French and foreign confreres can subscribe by sending a check of 680 francs to Dr Maurice Gerst general secretary 94 Boulevard Flandrin, Paris (16) This fee includes all expenses

BELGIUM

(From Our Regular Correspondent)

LIÉGE, June 7, 1922

Regulation Concerning the Sale of Disinfectants

To repress fraud and abuses in the sale of proprietaries which rely entirely on advertising for their existence the authorities have compiled regulations concerning the sale of disinfectants and antiseptics The containers must now bear a label indicating (1) the name and address of the manufacturer or person selling the product (2) its composition, indicated in usual terms regardless of the chemical formula, (3) the instructions for the various uses of the product and (4) its bactericidal value, especially the concentration, temperature and the time required to kill bacilli Pamphlets or advertising matter pertaining to these products must be identical with the label and contain only additional information that may be useful to the purchaser The retailing of disinfectants or antiseptics is limited to public drug stores All products not registered in the pharmacopeia, but sold as disinfectants or antiseptics, are subject to these regulations

Testing the Mentality of Schoolchildren

Dr Remy, chief inspector of hygiene of the ministry of the interior, recently, in the schools of Etterbeek made practical experiments before the members of the Belgian society of pediatrics by means of apparatus and procedures invented by him to test the fatigue and mental capacity of schoolchildren He had previously given to the society the results obtained during a course of research extending over more than seven years, and had shown how he can classify schoolchildren according to their mentality in a practical and rather accurate manner The apparatus and procedures conceived by him allow teachers to examine simultaneously all children in one grade and to establish the average of visual, auditive and tactile memories The age of children and results of their yearly school examinations furnish other averages Gifted children are above these averages, and the others are below Account was also taken, at the same time, of conditions that may influence the performance of pupils, on which depend not only advice as to choice of profession or life work and the assignment of scholarship funds to those who are better endowed but also, in the last analysis, the hoped for increase in productive capacity and the consequent uplift that will accrue to their country

Ovarian Grafts

Dr de Bruyn reported to the society of gynecology and obstetrics certain experimental facts as to ovarian grafts citing one clinical case in which fragments of ovaries were transplanted in the subcutaneous tissue of a woman of 25 after subtotal hysterectomy with bilateral ovariectomy The grafts hypertrophied, and ablation was performed 178 days after the operation, whereupon the menopause occurred Statistics from the Ghent clinic show that, in cases of hypertrophy of grafted tissue postoperative menopause disturbances are less frequent when there is no transplantation or when the graft is not larger than a pea On the other hand, a grafted fragment of the corpus luteum hypertrophies only in 20 per cent of the cases, a fragment of the medulla in 33 per cent and a portion of the cortical layer in 70 per cent The cortical layer seems to prevent disturbances of ovarian insufficiency more than any other tissues of the ovary Ovaries in which a grafted fragment had hypertrophied had a normal histologic aspect, those in which there was no graft, or a graft smaller than a pea, were composed mostly of sclerous tissues while in one, a woman of 40 the ovaries presented the histologic picture of a normal organ After 40, grafts never seem to hypertrophy

Death of Ernest Solvay

Although Ernest Solvay was not a member of the medical profession his life was too closely associated with it to let his death pass unnoticed He was an honorary doctor of the University of Brussels, and an eminent sociologist, and his generosity was proverbial His improved method for the manufacture of soda was a great economic achievement and he devoted a great part of his wealth to the foundation of scientific and social institutions He created the Institute of Physiology the Institute of Sociology and the School of Commerce in the University of Brussels, and he founded also the International Institute of Chemistry and the International Institute of Sociology

Exchange of Lecturers Between France and Belgium

The end of the academic year 1921-1922 was marked by the beginning of a new undertaking created after the armistice which is the consecration of the friendly ties uniting France and Belgium in every form of their activity The faculties of Brussels and Liege recently heard a series of lectures by French professors Gley spoke on endocrine glands, J L Faure gave motion picture lectures on his method of hysterectomy Picque demonstrated the usefulness of anatomy as applied to surgery by a series of twelve demonstrations, and Balthazard presented the problem of intoxication by carbon monoxid gas This first series of foreign lectures was much appreciated by students and also by physicians who attended in large numbers

Marriages

BEAUFORD IVAN PIPPIN Excelsior, Wis, to Miss Beba Nevada Hudson of Richland Center, Wis, April 6

LESTER EMMET TRETHEWAY, Manteca, Calif, to Miss Charlotte L Amarantes of Pleasanton, Calif June 18

KARL BUSBEE PACE, Greenville, N C, to Miss Lida Harrison Taylor of Goldsboro, N C, June 7

EDGAR JOSEPH CRAITE, Rich Lake, Wis, to Miss Margaret Sheedy of Green Bay, Wis, May 18

WALTER H SPOENEMANN, Chicago, to Miss Carol Stucke of Michigan City, Ind, June 17

PAUL PLEASANT COOPER, Zirkle, Ga, to Miss Sallie Williams of Patterson, Ga, June 3

VICTOR HUGO GARDNER, Dunnel, Minn, to Miss Florence Jack of Tomah, Wis, June 27

EMERY DON LUKENBILL, Portland, Ind, to Miss Treva Steed of Redkey, Ind May 8

WESLEY RAYMOND WELLS to Miss Flora S Monroe, both of Lake Forest, Ill, recently

HARRY EUGENE WILSON, Baltimore, to Miss Angelo Pauline Kehoe at Baltimore, June 24

LEE SANFORD SEWARD to Miss Eunice Smith, both of Ahwahnee, Calif, June 15

HUBERT ROGERS ARNOLD to Miss Agnes Ward, both of Oakland, Calif, recently

MAURICE E SHAMER to Dr Bertha E Tapman, both of Baltimore, June 18

B H ABEREMBT, Milwaukee to Miss Rosalia Sullivan, Wausau, May 18

EDWARD DUDLEY ALLEN to Miss Grace V Robeson, both of Chicago, June 14

RICHARD KOVACS to Miss Ina Clare Nickel, both of New York June 14

Deaths

Herman Tuholske ⊕ St Louis, Missouri Medical College, St Louis, 1870, formerly demonstrator of anatomy and professor of surgery at his alma mater, and professor of surgery at the Washington University Medical School, at one time physician-in-chief at the St Louis City Dispensary surgeon-in-chief at the Jewish Hospital, consulting surgeon at St John's Hospital, Jewish Home for Chronic Invalids and others, president of the St Louis Medical Society in 1908, died, June 12, aged 74, from chronic interstitial nephritis and hypostatic pneumonia

Winton Markwood Nihiser ⊕ Hagerstown, Md, College of Physicians and Surgeons, Baltimore, 1882, Bellevue Hospital Medical College, New York, 1885, formerly president of the Washington County Medical Society, served as surgeon for the Baltimore and Ohio Railroad for a number of years, was found dead in his office, June 17, with a bullet wound in his head, presumably self-inflicted, while suffering from ill health, aged 63

Edward Aaron Aronson ⊕ New York, Columbia University College of Physicians and Surgeons, New York, 1899, at one time instructor in the Fordham University Medical College and the College of Physicians and Surgeons, New York, formerly instructor in internal medicine at the New York Polyclinic Medical School, on the staff of the Mount Sinai Hospital, where he died while undergoing an operation, June 24, aged 47

John Cropper Wise ⊕ Medical Director, U S Navy, Washington, D C, Washington University School of Medicine, Baltimore, Md, 1869, entered the Navy as assistant surgeon April 28, 1870, and retired Oct 7, 1910, was fleet surgeon on the *Baltimore* of the Asiatic Fleet from 1897-1899, taking part in the battle of Manila Bay, formerly in command of the U S Naval Hospital, Washington, died, June 13, aged 73

Edison Burr Starr ⊕ Columbus, Ohio, Jefferson Medical College, Philadelphia, 1905, formerly director of industrial hygiene and medicine in the U S Public Health Service, at one time health director of Springfield, chief of the state division of industrial hygiene, died, June 19, aged 41, from typhoid fever

Reuben Lindsay Robertson, Charlottesville, Va, University of Virginia Department of Medicine, Charlottesville, Va, 1882, following his graduation he served in the U S Army for a period of twenty years, formerly city health officer, died, June 4, aged 62, at University Hospital, from septic pleurisy

George Howard Wilson ⊕ Mount Carmel, Ill, University of Louisville Medical Department, Louisville 1912, served during the World War in the M C, U S Army, with the rank of captain, specialized in radiography, coroner of Wabash County, died, June 19, aged 30, from carcinoma of kidney

Allen J Perkins, Lake Charles, La, Medical Department of the Tulane University of Louisiana, New Orleans, 1888, member of the Louisiana State Medical Association, coroner of Calcasieu Parish, died, June 20, from a bullet wound through the head, presumably self-inflicted, aged 56

Joseph Albert Hague ⊕ Alton, Fla, Georgia College of Eclectic Medicine and Surgery, Atlanta, Ga, 1913, formerly member of the state board of medical examiners, aged 38, shot and killed himself, June 12, in one of the rooms of his hospital

Martin V B Newcomer, Tipton, Ind, Medical College of Ohio Cincinnati, 1867, member of the Indiana State Medical Association, and the American Association of Railway Surgeons, died at the home of his daughter in Delphi, June 13, aged 85

Rosalie Bell ⊕ New York, Woman's Medical College of the New York Infirmary for Women and Children, New York, 1898, for six years an inspector of the department of health, died, June 14, at West Brighton, N Y, from heart disease

William Leo Mulcahy ⊕ Far Rockaway, N Y, Albany Medical College, Albany, N Y, 1903, on the staff of the St Joseph's Hospital, died, June 16, at the St Mary's Hospital, San Francisco, from cerebral hemorrhage, aged 40

Benjamin Franklin Abernathy, Danville, Tenn, College of Physicians and Surgeons of the Western District of New York, Fairfield, N Y, 1890, died recently, aged 72, from influenza and pneumonia

Harry Charles Gabriel, Athens, Ohio, Starling Medical College, Columbus, Ohio, 1894, member of the Ohio State Medical Association, died, June 2, at Beckley, W Va, aged 55, from heart disease

George Albert Libbey, Tacoma, Wash, Dartmouth Medical School, Hanover, N H, 1875, member of the Washington State Medical Association, died, June 18, aged 71, from cerebral hemorrhage

James O Bates, Grand Haven, Mich, Hahnemann Medical College and Hospital of Chicago, 1884, member of the Michigan State Medical Society, was found dead in his office June 17, aged 73

William M Richards, Joliet, Ill, Chicago Medical College, Chicago, 1876, died, June 17, aged 68, at the St Lukes Hospital, Chicago, from injuries received when he was struck by a street car

Cecil Stevens Cutler, Northampton, Mass, Medical Department of the University of the City of New York, 1877, formerly member of the city council, died, June 8, aged 71, from heart disease

Marshall E Cooksey, Etoile, Ky, Hospital College of Medicine, Medical Department Central University of Kentucky, Louisville, Ky, 1880, died, June 9, aged 82, from tuberculosis

Guy S Dunbar, Cleveland, University of Louisville Medical Department Louisville, Ky, 1915, member of the Ohio State Medical Association, died recently, aged 33, from pneumonia

Mark A Brawley ⊕ Frankfort, Kan, Cincinnati College of Medicine and Surgery, Cincinnati, 1873, formerly city health officer, veteran of the Civil War, died, June 16, aged 72

Charles Williamson Crumb ⊕ Utica, N Y, Medical Department of the University of the City of New York, 1886, died, June 18, aged 56, at his summer home in New Hartford

Arthur Otis McLaughlin ⊕ Haverhill, Mass, Tufts College Medical School, Boston, 1912, died, June 18, aged 42, at the Hale Hospital, from heart disease

⊕ Indicates Fellow of the American Medical Association

Edward F Bruce, Pensacola, Fla , Medical Department of the Tulane University of Louisiana, New Orleans, 1897, was found dead in his office, June 19, aged 45

George Louis Schmitt, Kansas City, Mo , University Medical College of Kansas City, Mo, 1898, aged 46, was shot and killed in his office recently by a patient

Albert H Felch, Beatrice, Neb , Hahnemann Medical College of Philadelphia, 1876, member of the Nebraska State Medical Association, died, June 3, aged 72, from paresis

William Bostick ⊕ St Louis, Kansas City Medical College, Kansas City, Mo, 1898, died, June 17, aged 45, at the Evangelical Deaconess Home and Hospital

James W Jenney, Salina, Kan , Western Homeopathic College, Cleveland, 1868 member of the Kansas Medical Society, died, June 14, aged 75, from pneumonia

William C McCurdy, Philadelphia, College of Physicians and Surgeons, Baltimore, 1874, died, May 20, aged 66, at the Philadelphia General Hospital

George Howe Winkler, New York, University of Georgia Medical Department, Augusta, Ga , 1881, died, May 23, aged 74, from cerebral hemorrhage

George W Meredith, Lincoln Neb , Indiana Medical College, Indianapolis, 1873, formerly member of the state legislature, died, June 15, aged 70

William F Bullard, Berrien Springs Mich , Medical College of Indiana, Indianapolis, 1880, died May 18, aged 73, following a long illness

George Heslop Grey, Rochester, N Y , Niagara University Medical Department, Buffalo, 1893, died, June 1, aged 50, from diabetes mellitus

Frederick James Barrett ⊕ New York, Columbia University College of Physicians and Surgeons, New York, 1905, died recently, aged 52

Kennett L Jones, Lewisburg, Tenn , Vanderbilt University Medical Department, Nashville, 1850, was struck and killed by lightning, June 12

Dennis Alphonsus Murphy ⊕ Gloversville N Y , Albany Medical College, Albany, N Y , 1904, died June 14, aged 41, from pneumonia

George W Vernon, Dexter, Mo , Central College of Physicians and Surgeons, Indianapolis, 1886, died, June 5, aged 64 from heart disease

Caswell A Atkins, Power Springs, Tenn , Medical Department University of Tennessee, Memphis, Tenn , 1899, died, June 13, aged 68

William Harper, Byron, Mich , Rush Medical College, Chicago, 1866, formerly a member of the state legislature, died, June 3, aged 79

L S Young, Moreland, Ga , Georgia College of Eclectic Medicine and Surgery, Atlanta, Ga , 1880 died, June 9, aged [illegible] from senility

Clarence S Latham ⊕ Hamilton Ohio, Starling Medical College, Columbus, Ohio, 1905, died June 2, aged 40, from heart disease

Wickes Washburn, Elizabeth N J , Medical Department of the University of the City of New York 1877, died, June 19, aged 68

Joseph Grant Wheeler, Jr ⊕ Bellevue, Pa , University of Pittsburgh School of Medicine, Pittsburgh, 1920, died, June 26

[illegible] Emmet O'Brien ⊕ Scranton, Pa Rush Medical College, Chicago, 1869, Civil War veteran, died June 14, aged 73

Allen M Riggs, Lafollette, Tenn , University of Tennessee College of Medicine, Memphis, Tenn 1893, died, April 5, aged 55

Samuel T Floyd, Kansas City, Mo , Missouri Medical College, St Louis, 1870, Confederate veteran died, June 1, aged 81

Joseph Clark Lackey ⊕ Jamestown Ohio, Ohio Medical University, Columbus, Ohio, 1896, died, May 16, aged 53

William S Taylor, Marrowbone Ky , Kentucky School of Medicine, Louisville, Ky , 1889, died, May 26, aged 63

Josiah S Wailes, Mystic, Iowa, College of Physicians and Surgeons, Keokuk, Iowa, 1889, died, April 16 aged 73

Clarence Augustus Stetson, Lynn, Mass Medical School of Maine, Portland, 1892, died, June 17 aged 61

Maria Allen Jessup, Farfield, Ind., Woman's Medical College, Chicago, 1887, died, May 5, aged 76

The Propaganda for Reform

IN THIS DEPARTMENT APPEAR REPORTS OF THE JOURNAL'S BUREAU OF INVESTIGATION OF THE COUNCIL ON PHARMACY AND CHEMISTRY AND OF THE ASSOCIATION LABORATORY TOGETHER WITH OTHER GENERAL MATERIAL OF AN INFORMATIVE NATURE

THE HILLSIDE COMPANY OF S W STAADS

Your Liberty Bonds or Cash Will Be Accepted to Exploit a German Cancer Cure—Twenty Per Cent Profits Assured

A Nebraska physician writes

I am enclosing a letter from the Hillside Company which was sent to me by a clergyman friend of mine whose letter I also enclose These letters are self-explanatory and you have his permission to make use of them if you care to do so '

The letter from the doctor's ministerial friend reads in part

I enclose a letter for your inspection I don t know where that institution got my name but I believe they want to soak a poor preacher

The enclosure itself is a mimeographed letter on the stationery of the Hillside Company, Sioux City, Iowa, and is signed "Dr S W Staads" It is written in German and the first paragraph reads

Dear Friend —It will be of interest to you as it will be to every friend of suffering humanity to know that German physicians have succeeded in their investigations to the extent that they have been able to prepare remedies that have cured the most difficult cases of cancer without operation In fact also patients who had been operated on in vain or who had received roentgen ray or radium treatment without success have been completely cured Through reading German medical literature and the kindness of my medical friends in Germany I became familiar with these remedies a number of years ago and I have now been positively assured that the rights to these remedies for the whole United States will be turned over to us under certain conditions Enormous prospects are thus opened up to us On the one hand this means a great boon for the cancer patients in our country and on the other hand such a concession for the whole United States means untold profits for us All physicians would gladly seize the opportunity if they knew of a cancer remedy that had been authoritatively approved '

The letter then states that it is the purpose of the Hillside Company to send a representative to Germany "to draw up the necessary contracts" which will doubtless result in the shares of the company rising considerably In the meantime this wonderful opportunity is given the "friends and acquaintances" of Staads to get in on the ground floor shares in the Hillside Company at $10 per share! Furthermore, Staads declares himself ready at the request of the purchaser to buy back these shares within two years of the date of issuance at the price paid for them and in addition, assures the purchaser a profit of 20 per cent *'Ich erklare mich bereit auf Wunsch diese Shares zwei Jahre nach Ausstellungsdatum, zum selben Preise zuruck zu kaufen und dass dieselben dann 20% eingebracht haben sollen"*

Any one who wishes to accept this "absolutely safe offer" (*"absolut sichere Anerbieten'*) must fill out the enclosed subscription blank and send it with cheque no later than May 25 'War Savings Stamps and Liberty Bonds will be accepted in payment at price we receive for them"

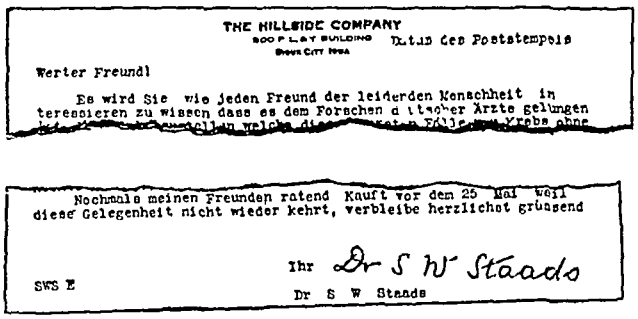
The Hillside Company is, apparently, a family affair, with S W Staads president his son-in-law, vice president and his son (a chiropractor it is said) secretary and treasurer The company is reported to be a "trust estate' with an authorized common stock of $200 000 and an authorized preferred stock of $150 000 How much capital has been paid in has not been learned

SOME EDUCATIONAL DATA

S W Staads' name appears in each issue of Polk's Medical Directories from 1900 until 1917 inclusive In each case it is a display announcement giving the alleged educational and professional qualifications In the directories for 1900 1902 and 1904 Staads is given as a graduate of the 'German Medical College of Chicago Ill , 1892 and of the "Independent Medical College, Chicago, 1899 The "German Medical Col-

lege," long since out of existence, was during its brief span repeatedly characterized by the Illinois State Board of Health as a fraudulent diploma mill It was operated by one Johann Malok who, according to the Illinois State Board of Health, 'profited by the wide-open incorporation laws of Illinois to the extent of securing charters for a brood of fraudulent diploma-selling institutions" The 'German Medical College" was not chartered until Dec 28, 1891, Staads was "graduated" in 1892!

The "Independent Medical College" was a fraudulent Chicago diploma mill whose charter was revoked by the Supreme Court of Illinois in 1899—the year of Staads' "graduation" The directory for 1906 and all subsequent issues contain no reference to Staads' "graduation" from the "Inde-



THE HILLSIDE COMPANY

Werter Freund!

Es wird Sie wie jeden Freund der leidenden Menschheit interessieren zu wissen dass es dem Forschen ärztlicher Ärzte gelungen

Nochmals meinen Freunden ratend Kauft vor dem 25 Mai weil diese Gelegenheit nicht wieder kehrt, verbleibe herzlichst grüssend

Ihr Dr S W Staads

SWS E

Photographic facsimile (reduced) of the opening and closing sentences of the letter of S W Staads in the latest attempt to sell stock

pendent Medical College", Staads still claims graduation from the "German Medical College"

In the same notices in Polk's directories we find Staads is also a "D P Chicago School of Psychology, 1897," and a "B S Chicago Seminary of Science, 1899!" In addition, he claims a 'special course Chicago Homeopathic Medical College, 1897," and "Pratt's Course of Orificial Surgery" over a period of years commencing with 1898 and adding to these years with each subsequent edition of the directory Of Staads' membership in medical organizations the directories showed

Member American Institute of Homeopathy
Missouri Valley Homeopathic Medical Association
Hahnemann Medical Association of Iowa
Sioux City Homeopathic Medical Society
American Association of Orificial Surgeons
Hon Member Nebraska State Homeopathic Medical Society

The directories also gave Staads as "Staff Surgeon, German Lutheran Hospital, Sioux City, and Lecturer to the German Hospital Training School, Sioux City, Iowa"

In the spring of 1911, following a discussion in THE JOURNAL regarding the "fee splitting" evil, a physician sent in a letter that he had received from Staads The opening sentence of the letter called attention to the alleged fact that Staads limited his "work to surgery and gynecology exclusively" and that he would "be pleased to take care of any surgical cases" that might be sent him Later in the letter Staads said

> Should a physician be paid for taking an operative case to a surgeon and for his assistance in such cases and for the responsibility and work he shares? He certainly is entitled to such recompense '

Whether this was a cryptic reference to the secret division of fees, we do not know, the physician who received the letter evidently thought that it was

THE SANITARIUM COMPANY

The Hillside Company is not the first stock-selling scheme of Staads' that THE JOURNAL has felt impelled to bring to the attention of its readers In this department for March 15, 1913, under the title "Another Get-Rich-Quick Scheme," the "Sanitarium Company" of Sioux City, Iowa, was dealt with The Sanitarium Company had for its president S W Staads Its alleged object was 'to manufacture and sell medicines for humankind and animals, chemicals, pharmaceuticals, infant and invalid foods, health coffees, to build and maintain a Sanitarium, etc"—a fair sized order German-Americans, preachers and physicians, were circularized, and a return of '22½ per cent on your money" and, in some instances, 35 per cent was promised to those who would invest

The prospectus declared that the Sanitarium Company had closed a contract with a German drug concern which would give it the exclusive right "to manufacture all of their products as medicines, chemicals, foods, etc, which have a tremendous sale in Europe" Nor was this exclusive concession limited to the United States it took in also Canada, Cuba, the West Indies, Mexico, Philippine Islands, and practically all South America As the prospectus naively said

> You will admit that with such large territory and such excellent preparations which have a great reputation where known we have a wonderful future full of the very best opportunities When thoroughly established in the United States through wide advertising to the physicians druggists and the laity we will gradually have to open branches in Canada Mexico Cuba South America the Philippines etc. Have you any conception of the wonderful possibilities of such work? Just think what it means to have thousands of physicians and druggists as shareholders as we intend to get! All shareholders are entitled to 10 per cent discount for cash on any direct purchase of our goods not marked net and on bills incurred at the proposed Sanitarium A 10 per cent discount means a good deal to the dispensing physicians and druggists and rest assured they will gladly buy from us all they can and recommend our preparations Does not that stand to reason? And that alone spells success

In addition, it was claimed that a large house had been bought in neighboring city (Cedar Rapids), this was going to be remodeled and turned into a "Hospital-Sanitarium' This institution, said the prospectus, would have an advantage over all others in the United States in that it would be the only one in which patients would be able to get the medicinal preparations made by the German concern whose exclusive rights the Sanitarium Company had obtained! As a subsidiary of the Sanitarium Company was the Physio Chemical Company, which put out a line of "patent medicines" These facts and others were given in detail in THE JOURNAL'S article which, in closing, expressed wonder as to how many physicians or 'Dear Reverends' would really invest good money in such a crudely and baldly exploited scheme"

The present scheme is just as crude and bald In order to get preachers and others to send in their Liberty Bond

35% im ersten Jahre sicher!

The Sanitarium Company

or their money Staads would have them believe that he can get the exclusive right to some made-in-Germany nostrum that will cure 'the most difficult cases of cancer"

Hookworm Disease in Brazil—A recent report by Belizario Penna shows that, from July, 1918, to September, 1921 about 300 000 persons were examined in the hookworm dispensaries In the federal district and neighboring territory, 236,890 persons were examined, 213,050 of whom were found infected with intestinal parasites More than 34,000 cases of malaria were treated A total of 616,451 hookworm treatments were given There were 34,682 persons vaccinated or revaccinated In some districts, the percentage of hookworm carriers varied from 31 9 per cent to more than 99 per cent Hookworm disease is an old disease in Brazil, where Wucherer and Silva Lima studied it, in 1860, under the name of intertropical hypohemia and tun-tun The hookworm work has lately been conducted under the direction of Dr Lewis Wendell Hackett of the Rockefeller Foundation In 1921 the federal and state appropriations reached $2,300,000, in addition to the annual expenditure of $250,000 by the International Health Board

Correspondence

PROPHYLAXIS OF VENEREAL DISEASE

To the Editor —I have read with interest the communication on this subject by Dr Herman Goodman, THE JOURNAL, June 24 He says, among other things, "The more prophylactics administered, that is, the more admitted exposures, the greater the incidence of venereal disease On the other hand, when opportunity for prophylaxis was reduced by curtailment of opportunity of exposures, the incidence of venereal disease became practically nil" This statement is followed by two imposing tables of statistics One can scarcely but suspect that the author has a subconscious bias against prophylaxis, perhaps for the same reason that the late Secretary of the Navy disapproved of it—that it licensed license The sense of the letter would appear to be that if men are prevented from indulging in intercourse they are not likely to contract venereal disease, a conclusion with which all must agree If one needed statistics to back this up the medical authorities of Sing Sing prison could furnish them

The reason that I call your attention to this matter is that I had not supposed that the American Medical Association was interested in the reduction of disease rate by the exercise of police power on the individual Conceding the fact that abstinence from sexual intercourse is a sure preventive of venereal disease, it appears to me that the enforcement of that abstinence lies in the province of individual morality rather than in that of preventive medicine

ARMITAGE WHITMAN, M D, New York.

"THE WILL TO BELIEVE"

To the Editor —I have received a number of letters approving the position I have taken with regard to the performances of Willetta Huggins, and others expressing, somewhat after the manner of the communications of Dr Babcock and of Dr Nagel in THE JOURNAL June 24 and 31, some reservations and a good deal of skepticism that sight sufficient to recognize colors should be possible despite a blindfold With some acquaintance with the blindfold performances on the stage, I can say that the "goggles" type of blindfold used in Chicago would be regarded as one of the "easiest"—that is, easiest to circumvent Sealing the eyelids with *opaque* court plaster, as suggested by Dr Babcock, would be completely effective, as would also be a number of other devices known to those who have given attention to the subject, and the tests in a completely dark room would also be made decisive Dr Babcock is entirely correct in citing examples of the unusual and expert use of senses by the blind and deaf, and I know of a number of instances more remarkable than those he cites But these cases do not function after the manner shown by Miss Huggins The question of excluding hearing is by no means so simple The experience of submarine detectors during the war seemed to show that nothing less than a device similar to a diver's helmet would answer Only an expert would be competent to determine just how far sound was excluded, though it is open to any one with normal hearing to apply a sound-excluding device and determine just how much he can hear and understand with it or despite it

There is no occasion to add anything in reply to Mr Hooper's public comment on the conclusions which I presented (New York *World*, June 17) and presented not as final but as a caution against the gratuitous hypothesis that the performance demands the assumption of 'smelling" colors or 'understanding" vibrations through the fingers, though it may be pertinent to indicate the apologetics which are needed to defend this strange conclusion To account for the failure, it is urged that the dark room at Madison was full of chemical odors which prevented the "smelling" of colors It did not prevent the "smelling" (?) of colors when a low light was on in the same smelly room, but only when that light was extinguished

Like Dr Babcock I am interested in having the matter determined beyond any doubt For this end I have prepared a set of tests which I should be glad to have any competent person apply in a wholly objective manner and unembarrassed by the presence of any advocate who believes that the performance requires a resort to extraordinary assumptions, or by the presence of a skeptic like myself who—as in the case of mediums who also claim unusual senses—is regarded as emanating unfavorable vibrations interfering with the exercise of the sense in question As I indicated in my article in THE JOURNAL, June 17, the psychologic laboratory has adequate methods and technic to bring the matter to a definite conclusion All that is needed is the cooperation of the subject and the determination of the conditions of the test by competent experimentalists I trust that this will be done in the near future Let it be understood that all depends on the technic and rigidity of the tests

JOSEPH JASTROW, Madison Wis

METHOD FOR UTILIZING ETHYL CHLORID IN LOCAL ANALGESIA

To the Editor —I wish to call attention to a simple but effective method of applying the ethyl chlorid spray for local analgesia I have used this method for the last four years in opening localized infections and in the fulguration of warty growths The reason that the freezing method as universally used is not effective is that the tissues are so hard that pressure enough to cause pain must be applied before the sharpest knife will cut through the frozen tissues The method I suggest is to apply the spray so as to form a circle around the area to be incised or fulgurated care being taken to keep the spray away from the center The width of the frozen area should be at least half an inch, and there should be at least 1 inch of unfrozen area in the center of the circle Blowing the breath on the freezing surface will be found to accentuate the freezing As soon as a white crust forms *all the way around* the incision should be made or the spark applied, immediately There will be very little if any pain, as this is essentially a nerve-blocking anesthesia RAYMOND L BRADLEY, M D, Houston, Texas

Queries and Minor Notes

ANONYMOUS COMMUNICATIONS and queries on postal cards will not be noticed Every letter must contain the writer's name and address but these will be omitted on request

TREATMENT OF CHEILITIS

To the Editor —I have a patient who suffers from peeling every summer owing I think to the effects of the sun as he is in the open all day The part of the lip affected is the mucous surface just posterior to the mucocutaneous junction I have tried everything I could think of without much benefit This trouble persists until cool weather and then subsides until the next summer Anything you might be able to suggest in the line of treatment would be appreciated The patient cannot protect himself from the sun He has to work in the open Plea e do not publish my name PHYSICIAN

ANSWER.—There are patients who have inflammatory reaction in the lips, cheilitis, from exposure to the sunlight It is difficult or impossible to overcome if exposure of the lips cannot be avoided, as is usually the case The use on the lips of a thick paste, made skin color with zinc oxid and calamine (or "crocus martis") as coloring would offer pro-

tection against the sun's rays, and if used persistently and frequently might be a great benefit When the patient is, as this one, a man, he might raise a walrus mustache, provided his mustache is heavy, which would give great protection from sunlight

PYROGALLIC ACID AS HAIR DYE

To the Editor —Is pyrogallic acid in a 2 per cent solution a safe hair dye for brown hair that is prematurely gray? A young woman in my practice comes to me with this question and I am unable to answer her If the pyrogallic acid is no good, kindly suggest something better Please omit my name SUBSCRIBER

ANSWER —Pyrogallic acid is not an entirely safe application as a hair dye It sometimes causes dermatitis, and poisoning has been observed from it It is usually used in combination with silver nitrate Probably as good a dye as any is paraphenylendiamin, which is the usual dye used for dyeing hair and furs brown or black This also, in susceptible persons, causes dermatitis, but not frequently There is no hair dye that is free from all risk

Miscellany

A GERMAN VISITOR'S IMPRESSIONS OF AMERICAN MEDICINE

Dr Hans Holfelder (*Klinische Wochenschrift* **1** 531 [March 11] 1922) gives an account of his visit to the United States a few months ago During his first short stay in Buffalo he was soon convinced of the efficacy of buried radium emanation in the treatment of malignant tumors, particularly cancer of the tongue and primary carcinoma of the rectum, whereas in metastases and recurrences it could not be used Just the opposite is true of the German method of roentgenotherapy He considers radium emanation as adapted only to primary tumors of the mucosa

In giving his impressions of American hospitals, Holfelder brings out the fact that they usually do not have *Chefarzte* (chief or head physicians) as in Germany but are open-staff hospitals in which a considerable group of physicians and surgeons work side by side He thinks that with America's vast wealth it would be destined soon to assume an unquestioned position at the head of the medical science of the world if it were not for the peculiar organization of the hospitals which not only militates against a uniform and systematic instruction of interns and assistant physicians and surgeons but also makes genuine research work more difficult The trouble seems to be that in the open-staff hospitals the interns are the assistants of from ten to twenty different physicians who belong to the staff of the hospital and that for this reason, they do not come under the influence of any particular school In some large cities, such as New York, the staff undergoes frequent changes throughout the year, which deprives the interns of the opportunity of continuous and systematic instruction The intern is responsible for the care of certain wards in which a large number of physicians treat their patients in a promiscuous manner Today the intern comes in contact with one physician and tomorrow with another, so that there is not the necessary continuity in the instruction he receives Another thing that makes this condition worse is the unevenness' which is characteristic of American universities and medical schools owing to the fact that they are not under state control However the classification of medical colleges as A, B and C schools has done a great deal toward remedying the unevenness of medical instruction, and will doubtless accomplish still more in the future Whereas the absolutely free competition that has prevailed in the past has been conducive to a high ethical tone, he sees in the operation of the Volstead act a grave menace to the morale of American physicians

He thinks the Ford Hospital at Detroit the most luxuriously appointed hospital he has ever seen, and as for cleanliness one could perform without hesitation an aseptic operation even in the furnace room However it seemed to him that the use of machinery to replace manual labor had been carried to extremes, and that the patients would be better off if the physicians were allowed more individual freedom

Holfelder referred to the recent endeavor of the Rockefeller Foundation to have the heads of departments receive adequate salaries but be deprived of the right to keep up their private practice He does not think that such a policy will lead to the desired goal, since most eminent clinical professors will prefer to renounce their professorial duties rather than their private practice It would also seem to involve a great risk for the character of the instruction if a professor is deprived entirely of the personal contact with patients, which has such a stimulative effect on clinical instruction

Holfelder noted that the results of laboratory tests play a much greater role for diagnosis and therapeutic indications than is the case in Germany The methods of performing laboratory tests have been so simplified that it has become possible to utilize them on a large scale, but he thinks it would be well for Germany to adopt certain features of American laboratory methods However, he fears that one result of such extensive application of laboratory tests has been that the clinical examination of the patient has sometimes been relegated to the background to such an extent as to prove harmful to the patient Especially does this seem to be true in the case of physicians who have not enjoyed the advantage of the first-class medical schools This condition will be improved when all medical schools have been brought up to the high standard of the best In regard to the claim that in a large percentage of cases, rheumatic symptoms can be traced to a focus of infection in the teeth or mouth Holfelder is somewhat skeptical He admits that the relationship between a focus of infection in the mouth and rheumatic pains in some distant organ may not have received in Germany the attention it deserves, but he feels equally sure that such a relationship is being assumed in America much more frequently than the facts will warrant

He was much impressed with the system of blood transfusion as practiced in America, and especially with the organization of details so that in an emergency case only ten minutes was required to have a donor of the proper blood group on hand ready to furnish up to 1,000 c c of his blood While he feels that many lives are thus saved, there may be a tendency to overdo the matter

CHILDREN OF WAGE-EARNING MOTHERS

A report of the U S Department of Labor entitled 'Children of Wage-Earning Mothers A Study of a Selected Group in Chicago," states that gainful employment of mothers of young children frequently means that the children receive inadequate care during the day The report presents the results of a study of 843 families of working mothers in which were 2066 children under the age of 14 years This included 212 colored families The forty-five day nurseries in Chicago were not maintaining high standards with respect to sanitation and child care, and only two nurseries with a capacity of twenty each, were available to colored children Retarded school progress of the children overfatigue and ill health of the mothers with consequent loss to the children and in some instances overwork by children who had the responsibility for household tasks beyond their strength, were other conditions found More than one third were found below the standard grade for their age in the schools Measures will be taken for reducing the necessity for wage earning by mothers of young children These measures will include an improvement of economic conditions that will make the fathers' earnings more nearly adequate, training of mothers in household management and the care of children preserving the normal family group through movements for the prevention of accidents and the promotion of health and providing substitutes for the father's support, at his death or when he is incapacitated by means of mothers pensions and aid from social agencies

THE RELATION OF GAS POISONING TO TUBERCULOSIS

Ex soldiers who were exposed to poisonous gases during the World War have been led to believe that they are likely to develop tuberculosis as a result of such exposure Hence, although in good health they are constantly watching for symptoms of consumption Neither fact nor sound opinion affords any basis apparently for this fear An investigation of this subject was made by the Chemical Warfare Service and the results have been published The investigation covered experiments with mustard gas and phosgen on laboratory animals a study of 2000 gas cases by a board of officers, the views of many officers of large experience in treating gassed soldiers and a study of the reports of several European countries

It was stated in the British report that tuberculosis does not develop more frequently in gas victims than in other subjects" A similar view was held by the French, who said, "Judging from experience, it does not seem that lung lesions

caused by gassing predispose to tuberculosis" The Germans reported that their "physicians unanimously agree that gassing has no connection with tuberculosis"

The Chemical Warfare Service concluded its investigation by saying 'It is far from convincing that gas played any particular role in this connection, and it is doubtful if the incidence of lung tuberculosis among ex-service men is much greater by reason of the part that gas played Those who claim to have developed tuberculosis a year after leaving the service, from conditions experienced in the army, certainly have no basis for such assertion They probably would have become tuberculosis patients even if they had never been in the army There are two elements entering into this problem—one neurasthenic, where the men were gassed, usually very slightly, and believed sincerely that this was a factor in their illness, and second, mistaken diagnosis in many cases, especially those following influenza, in which instances of unresolved bronchopneumonia occurred leaving nodular patches on which the diagnosis of tuberculosis was frequently based on roentgen-ray plates"

Book Notices

VÆ INVENTORIBUS MAGNIS Por el Dr Angel Pulido Fernandez V Presidente del R C de Sanidad Academico Paper Pp 524 with illustrations Barcelona Imp La Renaixensa 1921

PRECURSOR REPRESENTATIVO Y MÁRTIR Por el Dr Angel Pulido Fernandez V Presidente del R C de Sanidad Academico Paper Pp 496 with illustrations Madrid Imprenta del Instituto Nacional de Sordomudos y de Ciegos 1921

These two books by the venerable president of the superior board of health of Spain, are an eloquent disproof of the old saying that no man is a prophet in his own country Both, printed at the expense of the government, take up most minutely, perhaps too much so, the achievements of Dr Jaime Ferran the scientist, whom the author calls a pioneer in many remarkable medical advances In fact, Dr Pulido aims to prove that the whole fabric of modern vaccination, both preventive and curative, has its origin in Ferran's anticholera work in 1885 The first book goes in detail into the cholera epidemic in 1885, Ferran's discovery of vaccination as a prophylactic, the attacks made on anticholera vaccination and typhoid inoculation (also introduced by the Spanish bacteriologist before Wright), the unfavorable reports made at the time by the French and Spanish Commission, Cajal's scornful attitude toward the new method, the favorable change in foreign opinion as represented by Klemperer, Guttmann, Roux, Metchnikoff, Calmette and Ehrlich, and finally what he calls Ferran's martyrdom, i e the neglect toward the investigator, who was even expelled from his position as head of the municipal laboratory of Barcelona, although this apparently was due to poor administrative methods on Ferran's part The second book deals especially with Ferran's present theory of tuberculosis and the trial of his antialpha vaccination in Palma de Mallorca and elsewhere No one could read these well written if prolix books without a feeling of admiration for their gifted author or respect at the sense of duty which impelled him, at the age of 69, following recovery from a serious disease, to devote all his energies to Ferran's defense and panegyric After wading, however, through 1 020 pages filled with encomium satire, literary quotations, attacks on Cajal, reports and speeches, and lacking in actual statistics, one cannot escape the conviction that the story would have gained by being told more concisely and systematically, that Ferran s own peculiarities and lack of business acumen may have had a great deal to do with his tribulations, that his theory may have been better than his practice, that Cajal's reservations may have been only too well founded and that after all Ferran s conception of the duality of the tubercle bacillus is still *sub judice* Why make a martyr out of a man who has found thousands of people to submit to his antituberculous inoculations, has his own laboratory, plenty of patients a number of followers in South America who call him master, has just been given 50,000 pesetas by the government for his antituberculosis work and, above all, has such an able and earnest advocate as Dr Pulido to sing his praises in two thick volumes published by the Spanish government?

DISEASES OF WOMEN By Ten Teachers Under the direction of Comyns Berkeley M D M C Obstetric and Gynaecological Surgeon to the Middlesex Hospital Edited by Comyns Berkeley H Russell Andrews and J S Fairbairn Second edition Cloth Price $10 net Pp 641 with 223 illustrations New York Longmans Green & Co, 1922

A book written by several men in collaboration rarely exhibits unity of purpose or sustained excellence For this reason one will be agreeably surprised to find how rigorously in this book the individuality of the authors has been subordinated to scholarly production At the same time the mechanical workmanship has not been neglected The plates and illustrations are informative, and the index is a joy in its meticulous execution The order of the subjects is excellent and the text is consistent, logical and clear The book is written from the standpoint of the ideal surgeon who is not only openminded but also broad through a mature familiarity with all available resources of our profession It is a pleasure to come across a treatise which is not disfigured by dogmatism, useless verbiage or futile speculation over exploded or undeveloped hypotheses Though many of us would be gratified by a somewhat more elaborate and detailed description of the operative technic, it is remarkable how adequately this section has been covered in the allotted fifty pages It would seem to show that ordinarily much space is wasted in duplication or verbosity The portion devoted to infections has also been stripped to the bone and yet the theme advances with marvelously little sacrifice of important matter A novel and valuable feature is the inclusion of the chapters on appendicitis and acute conditions of the abdomen as definite gynecologic maladies rather than as complications of more generally recognized conditions The pathology in these cases is so obviously intertwined with the pelvic disorders that we wonder why they have not been admitted heretofore into a frank fellowship In an effort to imitate the authors in the clarity and succinctness of their style, we may say that the book is a masterly condensation of the principles and practice of modern gynecology, an invaluable compendium for both the student and the practitioner

GRUNDRISS DER KLINISCHEN THERAPIE INNERER KRANKHEITEN Von Prof Dr Georg Klemperer Direktor der IV medizinischen Universitätsklinik Arztl Unter Mitwirkung von Oberarzt Dr L Dunner Paper Price 108 marks Pp 237 Berlin Urban & Schwarzenberg 1922

Only a clinician of the widest bedside experience could have written such a book as this The volume is based on the assumption that the first element in therapy is correct diagnosis, and the book is intended only for those capable of making correct diagnoses Throughout it stresses the necessity of attention to the details of the individual case, for all patients, no matter what the disease the mind must be kept at rest, the surroundings agreeable and composed, the food appetizing It is really interestingly written which is saying a great deal for a book of therapeutic opinions One notes certain omissions for instance, the absence of a discussion of protein sensitization in bronchial asthma and its therapeutic indications The casual remark on serum therapy in pneumonia leaves one in much doubt To those American readers who are accustomed to consider the treatment of gastric ulcer as possible along only one royal road, we particularly commend Klemperer's interesting discussion The treatment of diabetes mellitus used for a long time by Klemperer will evoke a sympathetic response in the followers of the new slogan, 'low protein, high fat'

A PSYCHIATRIC MILESTONE Bloomingdale Hospital Centenary 1821 1921 Cloth Pp 220 with 6 illustrations New York The Society of the New York Hospital 1921

This volume printed in 1921, marks the hundredth anniversary of the Bloomingdale Hospital and Asylum It includes an historical review and addresses by a number of noted neurologists who took part in the anniversary celebration

Medicolegal

Disability from Typhoid Fever Caused by Drinking Polluted Water

(Hasmuth Endicott Co Karst (Ind) 133 N E R 609)

The Appellate Court of Indiana, in affirming an award of the industrial board, under the workmen's compensation act, in favor of plaintiff Karst, says that there was substantial evidence tending to establish that he was in the employ of the defendant company in its factory, where drinking water was furnished from a well, through pipes, it being pumped by stream, and flowing constantly during working hours Without the company's knowledge, the water became contaminated by seepage from a toilet in the factory The plaintiff used the water for drinking purposes, without knowledge of such pollution, and became infected with typhoid germs, by reason of which he had an attack of typhoid fever On this evidence the industrial board found that he received a personal injury by accident arising out of and in the course of his employment

This court, in determining questions of liability under the workmen s compensation act, has adopted the definition that an accident is any unlooked-for mishap or untoward event not expected or designed" Applying this definition, it is clear that the entering of typhoid germs into the plaintiff's intestines, by reason of his drinking the polluted water furnished him by the company for that purpose while in its employ, might rightfully be termed an 'accident" The next question was as to when the injury could be said to have occurred It has been said that in common speech, the word "injury," as applied to a personal injury to a human being, includes whatever lesion or change in any part of the system produces harm or pain or a lessened facility of the natural use of any bodily activity or capability When that definition is applied to the facts of this case, it is not difficult to determine when the injury resulting from the accident in question occurred It is well known that typhoid fever is due to a specific micro-organism, known as the typhoid bacillus The bacillus sets up a catarrhal inflammation of the mucous membrane of the intestines causing ulcers and fever When this occurs, the victim evidently sustains an injury The typhoid bacillus, when taken into the intestines, does not always create a catarrhal inflammation If it does not, no fever follows, and no injury is sustained In this case however such an inflammation occurred, with resulting fever, constituting an injury within the meaning of the workmen's compensation act

Nor can it be said that the decision in this case is not in harmony with the limitation of the Indiana statute that "'injury' and 'personal injury' shall mean only injury by accident arising out of and in the course of the employment and shall not include a disease in any form except as it shall result from the injury" It is obvious that, in any given case involving disability so resulting, the inquiry must always be, Did the disease result from an injury by accident, arising out of and in the course of the employment? The injury, however need not be produced by violence as the Indiana statute unlike the statutes of some other states does not so provide It suffices in that regard whatever the accident may have been, if it produces a lesion or change in any part of the system which injuriously affects any bodily activity or capability When this occurs, and disease follows causing disability, the right to compensation is not affected by the statutory limitation quoted But it must be borne in mind that the injury must be by accident arising out of and in the course of the employment This limitation alone will have the effect of preventing a recovery of compensation for disability resulting from diseases generally, as it is clear that a disease contracted by an employee through such usual intercourse with his fellow workmen as is common among men and not because of any unusual circumstances connected with his employment, cannot be said to be an accident within the meaning of the workmen's compensation act The fact that the accident involved in this case occurred while the plaintiff was engaged in quenching his thirst, rather than in the actual performance of some duty which he owed the defendant under his employment, was not a matter of controlling importance, as it is recognized that such acts as are necessary to the life, comfort, and convenience of the workman while at work, though personal to himself, and not technically acts of service, are incidental to the service, and an accident occurring in the performance of such acts is deemed to have arisen out of the employment

Power to Quarantine Typhoid Carriers

(People ex rel Barmore v Robertson et al (Ill) 134 N E R 815)

The Supreme Court of Illinois, in remanding the relatrix to the custody of the respondents says that the latter were the commissioner of health and an epidemiologist of the department of health of the city of Chicago, from whose alleged unlawful restraint of her liberty at her home as a typhoid carrier the relatrix sought release through habeas corpus She had been keeping roomers and boarders when information came to the department of health that several persons who had previously roomed and boarded at her house had been ill with typhoid fever She submitted to the department specimens of feces, an examination of which revealed large numbers of typhoid bacilli, but she testified that she had never been sick with typhoid fever, that no member of her family and no boarder or roomer had ever been sick with typhoid fever while living with her and that so far as she knew no one had contracted the disease by contact with her The department of health placed her and her house under quarantine, placing a large placard on the house warning all persons that a typhoid carrier resided in the house The quarantine regulations prescribed required her to remain in her home and forbade her to prepare food for any one but her husband, and forbade any one to come into her home as roomers or otherwise, unless they had been immunized from typhoid fever

It is not necessary that one be actually sick as that term is usually applied, in order that the health authorities may have the right to restrain his liberties by quarantine regulations Quarantine is not a cure, it is a preventive As the term is used in this opinion, quarantine is the method used to confine the disease within the person in whom it is detected or to prevent a healthy person from contracting the infection Disease germs do not usually travel through the air unaided but they are carried by insects by dumb animals and by human beings Effective quarantine must therefore be not so much the isolation of the person who is sick or affected with the disease as a prevention of the communication of the disease germs from the sick to the well Thus in the case of typhoid fever, effective quarantine must include very strict restrictions on the movements of the attendants who in any way come in contact with the sick person or his discharges It must include the destruction of the bacilli in the feces and the urine and in the cloths used to wipe the mouth of the patient Quarantine in the very nature of the regulation, is not a definite uniform measure, but it must vary according to the subject One of the important elements in the administration of health and quarantine regulations is a full measure of common sense

In the case at bar the state board of health, or a board of health in the city of Chicago duly organized pursuant to the authority given the city council by the legislature, would undoubtedly have the right to establish reasonable quarantine regulations with respect to the relatrix, so long as she was discharging the germs of a contagious and infectious disease Whether the authority exists to compel a person apparently well to submit to an examination to determine whether he is a germ carrier was not before this court for the reason that the relatrix submitted to the examination which revealed that she was such a carrier The only question presented for determination was whether she was legally and properly detained under quarantine in her home The statute gives to no such individual as the health commissioner of Chicago authority to make rules and regulations which shall have the effect of law, and the city has no right to give him authority to determine when a contagious and infectious disease exists and to establish a quarantine His

authority is limited to carrying into execution orders of a legally constituted board of health But the department of health of Chicago reported the case of the relatrix to the state department of health, and requested that department to authorize a modified quarantine, which authority was granted, so that the respondents were restraining the relatrix as agents of the state department She was bound to respect the rules and regulations promulgated by the state department of health respecting the modified quarantine under which she was placed, and for a violation of these rules she was subject to the penalties provided by the statutes In order that she might know what the rules and regulations were, it was necessary that she be furnished a copy of them

Sufficient Authority and Statement for Services

(Dalton v St Louis & S W Ry Co (Mo) 238 S W R 525)

The Springfield (Mo) Court of Appeals in affirming a judgment against the defendant railway company for services rendered by the plaintiff as a physician to one Monigold, says that Monigold was found on the right of way of the defendant with one foot and leg badly crushed No one saw the accident, but it was inferred that the injury was caused by a passing train The station agent called the plaintiff over the telephone and asked him to attend Monigold The plaintiff went, and found the man loaded in a wagon to be taken to his office The plaintiff was at that time, and afterward, told by the assistant claim agent of the defendant to treat Monigold and in pursuance with that direction as well as the call from the station agent, he performed the service which was the basis of this action The leg was amputated below the knee, with the assistance of the defendant's regular physician who was out of town when the plaintiff was called After the amputation, the patient was taken in charge by the defendant's physician, but the plaintiff continued in consultation with him until the patient recovered The plaintiff filed this statement before a justice of the peace

March 9 1920

St Louis & Southwestern Ry Co to Dr George Dalton Dr
March 9 1920 To professional services rendered as per request on J W Monigold $200 00

The sufficiency of the statement was challenged by the defendant The test of its sufficiency was Did it notify the defendant with reasonable certainty of the nature of the cause of action it was required to meet, and would it bar another action on account of the same subject matter? Measured by this standard, the court thinks the statement was sufficient

The next contention was that there was no evidence that either the station agent or the assistant claim agent had authority to employ the plaintiff, and thereby bind the defendant, and that the employment itself did not constitute a binding contract If the employment was authorized the law would imply a promise to pay the reasonable value of the services rendered, in the absence of an agreement as to the price to be paid The station agent testified that he had authority to employ a physician in an emergency to attend passengers or employees, and that was the only evidence relating to his authority, while there was no evidence that the injured man was either a passenger or an employee, so that the evidence did fail to show authority in the station agent to make the employment But the evidence as to what the station agent did was competent to show how the plaintiff was induced to begin the service to the injured man in connection with what he testified took place immediately thereafter between him and the assistant claim agent The assistant claim agent testified that his business was to investigate the facts when injuries occurred, and that he had no specific instructions as to what to do in relation to employing physicians, but that he used his own judgment in emergency cases This in connection with what he did in this case, was sufficient to take the case to the jury on the question of his authority to act for the defendant in the emergency under which the plaintiff was employed by him in this case In short, the court does not think that there was any evidence that the station agent had authority to employ the plaintiff to attend Monigold, that the question of the assistant claim agent's authority was a close one on the testimony, and that the jury must have based their verdict on a finding that the assistant claim agent, and not the station agent, had the authority and did employ the plaintiff

Sale of Practice—Issuance of Prescriptions

(Clabaugh Heibner et al (Mo) 256 S W R 396)

The Kansas City (Mo) Court of Appeals, in reversing a judgment obtained by the plaintiff on a note, says that the note was given as part of the $800 consideration for which the plaintiff, a physician, sold his office fixtures, buggy, practice of medicine and good will thereof, in a stated community, to another physician, who will be called the defendant, the plaintiff agreeing that he would not directly or indirectly enter into or engage in the practice of medicine in the city where he had been located, or the country immediately adjacent thereto, as long as the defendant should be engaged in the practice of medicine in the city in question In a counterclaim, the defendant set up that the plaintiff had violated the agreement, and, on this account, damages were asked, less the amount due on the note The execution of the note being admitted, the burden was on the defendant to establish his counterclaim The plaintiff, who subsequently located in a neighboring city, admitted that after the maturity of the note he had practiced in his old location, and about three weeks after the maturity of the note he wrote to the defendant The practice I have done is practice that refused to employ you" So, the court goes on to say, it was beyond question that the plaintiff did practice medicine in that community in violation of his contract not to do so

It is well settled that contracts of this nature are valid The good will of a business is a species of property, a thing of value which may be bought and sold, and which the law will protect awarding damages for injuries thereto The trial court, however, confined the defendant to evidence of the plaintiff's practice prior to the maturity of the note, and would not allow evidence to be offered as to practice after that date on the theory that the failure to pay the note when due was a breach of contract on the defendant's part which authorized the plaintiff to disregard the provision obligating him to refrain from practice in that community That was error There was no provision in the contract that a failure to pay the note when due would render the terms of the contract void or have any effect thereon The nonpayment of the note when due was merely a default in the payment of that obligation not a breach of the other contract Besides, the failure of the defendant to pay the note when due may have been due to the plaintiff's prior violation of the contract

In addition to evidence of professional visits and practice carried on by the plaintiff in or around the city where he was first located the defendant introduced 120 prescriptions issued by the plaintiff to patients residing in the city in question and within eight miles thereof These prescriptions were filled at a drug store in this city The issuance of prescriptions in which a physician prescribes remedies he deems appropriate for ailments or diseases is practicing medicine. But the question here was, Where was the practice, in issuing such prescriptions, carried on? It would seem that, if patients went to the plaintiff's office in the other city and consulted him and were examined treated or received prescriptions there such acts on the part of the plaintiff would constitute practicing of medicine in the other city, even though the patients in question may have resided in or around the city of his first location and have taken such prescriptions to the latter place where they were filled But if the prescriptions were issued under such circumstances as that, either the giving of the prescriptions, or the consultations with or examination of the patients to whom they were given could be said to have been consummated in or around the city of his first location, then such practice was not in the other city, but within the territory of the contract

SOUTH DAKOTA STATE MEDICAL ASSOCIATION

Forty First Annual Session held at Huron May 16 18 1922

The President, DR G S ADAMS, Yankton, in the Chair

Syphilis in General Practice

DR A A MCLAURIN, Pierre The spirochete has invaded the lymph and blood streams before the primary lesion develops Any lesion of the external genitalia, regardless of its appearance or duration should be considered syphilitic until proved otherwise Caustics applied to these lesions delay the diagnosis and expose the patient to unnecessary danger

Practical Suggestions in Diagnosis and Treatment of Pulmonary Tuberculosis

DR F W WITTICH, Minneapolis The patient should rest for half an hour before and after meals, should take the temperature and pulse before arising in the morning, or, if remaining in bed at 7 30 a m and at 4 and 8 p m, and should remain in bed for at least six weeks or until the temperature and pulse are normal and there is a gain in weight Before taking exercise by walking, he should commence activities by going to the evening meal If the temperature remains normal at 8 p m, he should go to two meals and finally to all three If there is a rise, he is exceeding his exercise and must remain in bed until it remains normal for three days Before walking exercises are begun, he should try to dress himself try sitting in a reclining chair out doors as much as possible and going to meals After doing this for several days without increase in cough or expectoration, and temperature and pulse, he should begin to take fifteen minute walks in the middle of the forenoon He should return to bed or recline in the chair and take the temperature and pulse at once, rest for half an hour, and take them again If they are above normal it means that he is exceeding his exercise He should be weighed each week if possible when on exercise Between the walking exercises he should remain in the open as much as the weather will permit He should go to bed every afternoon after lunch until 4 o'clock Lunches consisting of a glass of milk, buttermilk malted milk and crackers may be taken at 10 30 a m and 4 p m The voice should be rested as much as possible, also the lungs, by avoiding long conversations When the voice is hoarse and the throat sore, he should whisper He should be in bed with the lights out at 9 p m The patient should try to avoid crocheting letter writing, and even reading for at least an hour after the noon meal The cough should be controlled as much as possible, and gauze or a paper napkin held in front of the mouth when coughing These should be placed in a paper bag pinned to the mattress at the head of the bed, and burned each day The dishes should be washed and scalded separately

Relation of Laboratory to Clinical Medicine

DR J C OHLMACHER, Vermilion A few of the things that make for the ideal in group and hospital practice are (1) The union of medical men in the various spheres of medical activity whose paramount interests concern the welfare of the patient and the scientific and ethical advancement of their profession (2) Thorough and up-to-date equipment in clinic and wards (3) An up-to date library (4) Holding weekly or semiweekly conferences at which cases may be discussed, and topics of interest concerning new scientific medical advancements considered (5) Encouragement of clinical and laboratory investigations (6) Establishment of a completely equipped laboratory where all the usual routine and the newer methods of laboratory diagnosis and original research may be carried on under the supervision of a competent pathologist (7) Recording and filing of case histories, including clinical findings, laboratory findings, treatment, necropsy findings, etc, and the publication of papers in reference to cases of special interest, and articles covering clinical and laboratory research or the publication of a yearly or biennial bulletin containing matters of interest or value to the profession There is a great need to standardize laboratory methods Those having charge of laboratories should be licensed by some governing agency capable of raising and maintaining the standard of requirements to such a degree as to weed out all incompetents

Inflammatory Conditions of the Mastoid Process and the Middle Ear

DR A A SORENSEN, Aberdeen There are two common forms of acute middle ear inflammation, in both of which the subjective symptoms may be identical and the indications for treatment very similar The first is that known as acute catarrhal otitis media, generally related to such affections as rhinitis and influenza, to septic hypertrophied adenoid tissue in the nasopharyngeal vault, or to the presence of certain micro-organisms, being commonly an extension of a nasopharyngeal infection through the eustachian tube, and capable of assuming a subacute or even chronic form A second form is acute purulent or suppurative otitis media, which is always of bacterial origin often resulting from the entrance of such organisms as the pneumococcus, staphylococcus streptococcus or influenza bacillus into the tympanic cavity by way of the eustachian tube, where they produce inflammation Such micro organisms are often associated with such a general systemic infection as pneumonia or typhoid or may result from a tonsillitis or septic nasopharyngitis

Recent Developments in Radiotherapy

DR R F BELLAIRE, Sioux City, Iowa Surgery should take precedence over all other forms of treatment unless the case is inoperable then surgery is secondary to the roentgen ray or to radium Deep therapy with the roentgen ray is in a very vital period of transition To kill deep seated growths it is absolutely essential to introduce into the deep structures a 100 per cent dose The ratio between the skin and depth dose must be about equal In certain forms of sarcoma the ratio may be as low as 60 or 80 per cent of the total skin dose For the production of deep lethal doses, tremendously high voltages must be utilized Of all the factors concerned, high voltage is the most indispensable, because voltage determines the force with which the rays are projected into the tissues The higher the voltage, the shorter the wave length, the shorter the wave length, the greater the velocity of the rays If, therefore, sufficient voltage can be generated for the introduction into the deep parts of lethal doses without destroying the overlying skin, we shall have advanced tremendously toward the solution of the cancer problem

Complications of Prostatectomy

DR FRANKLIN R. WRIGHT Minneapolis Complications of prostatectomy naturally divide themselves into three groups those which occur at the operation, those which occur immediately following operation and those which take place during the healing process Those which occur at the time of the operation are the accidental opening of the peritoneum, and hemorrhage This accident is not of serious nature Hemorrhage at the time of operation may be anything from a slight loss of blood to one which threatens the patient s life Troublesome hemorrhage may come from the edge of the bladder mucous membrane where during the enucleation the urethral mucous membrane was torn from it, or may come as a general oozing from the surface of the cavity from which the tumor was enucleated Neither of these two forms is serious The third form of hemorrhage is of serious

nature If, in attempting to enucleate the tumor from the prostate, the prostatic sheath is torn, a venous plexus is torn, and the hemorrhage is alarming The prognosis in these cases is not good We can control hemorrhage, but as virtually all these bladders are septic, the clots which form under the packing in the torn veins become septic, and patients die of general sepsis about the fifth or sixth day Complications immediately following operation are uremia, reflex conditions and infections

Pathogenic Ptosis of Right Colon

DR E P QUAIN, Bismarck, N D Coloptosis is a very common anatomic abnormality Comparatively few coloptotic patients suffer serious symptoms Some of the effects of coloptosis are translated to other abdominal organs which may then give rise to a new set of symptoms based entirely on the complication, and obscuring the original and chief cause Medical treatment gives relief in most cases and should be given thorough trial in all cases, but its ability to cure is doubtful in any case Surgical treatment is as successful in these lesions as in many other so-called surgical diseases and promises better results as experience accumulates

Pyuria in Infancy and Childhood

DR HENRY F HELMHOLZ, Rochester Minn I use the term pyuria rather than pyelocystitis or pyelitis because often pyuria is the only diagnosis permissible from the symptoms and physical findings The pus may be obtained from the vagina, urethra, bladder ureters, pelvis or substance of the kidneys Catheterization merely discloses the presence or absence of inflammation in the bladder or urinary tract above It seems hardly justifiable, in view of the relatively benign course of most infections of the bladder and kidneys to make general use of ureteral catheterization in infants and children Occasionally the tuberculosis bacillus alone may give rise to pyuria, although in the majority of cases the colon bacillus is present as a secondary invader Sometimes cases are observed in which the cultures are sterile and the possibility of a tuberculous infection can be excluded by stains, cultures and animal inoculation, even though there are large amounts of pus in the urine Pyuria may be part of a general pyemic process with numerous abscesses in the cortex or medulla of the kidneys Sometimes these abscesses occur only in the kidneys and give rise to a severe type of pyuria, closely resembling pyelitis and to be distinguished from it only at necropsy Pyuria is virtually always produced by hematogenous infection localizing in the renal cortex and forming abscesses which, on draining into the pelvis, may set up pyelitis A second type of renal involvement is that secondary to the usual pyelitis which, after running a rather chronic course, suddenly becomes extremely acute The process is a pyelonephritis without abscess formation resulting in a complete shut-down of the kidney A third type of disease of the kidney is that associated with the damming back of the urinary flow due to obstruction from any cause, and a localized breakdown of the substance of the kidney into multiple abscesses A fourth type of involvement is ordinary primary pyelitis, which unquestionably is very much more common among girls A fifth type is pyuria secondary to infections other than those in the urinary tract, following tonsillitis, bronchitis otitis and other pyogenic infections This type, usually recognized only by examination of the urine, there being practically no symptoms pointing to involvement of the urinary tract and increased temperature if present is assumed to be due to the primary infection Water is the most important single item in all treatment For infants 1 year old fluid intake should reach from 1½ to 2 quarts every twenty-four hours If necessary, fluids may be given by rectum, or by intraperitoneal subcutaneous and intravenous injection Infants may also be given sodium citrate and sodium bicarbonate, 60 grains in twenty-four hours, the dose may be doubled every forty-eight hours until the urine becomes alkaline. In certain cases hexamethylenamin and acid sodium phosphate may be used Local treatment by ureteral catheterization and pelvic lavage may be tried as a means of last resort

Decreasing Diabetic Mortality Increasing Incidence of Glycosuria E P Joslin Boston —p 761
*Divided Meals for Severe Diabetics H Gray Boston —p 763
*Advantage of Multiple Meals in Treatment of Severe Diabetes T Murayama Boston —p 768

Divided Meals in Diabetes—The theory of divided meals appears to be activation of the liver or pancreas by a small, preliminary meal of carbohydrate given one or two hours before each main meal, the organism being then in action at the time of that regular meal responds to the food load more vigorously than with the everyday three meal schedule The results obtained by Gray indicate that the method does help to lower the blood sugar The method is, therefore advocated by him as having practical value

Multiple Meals in Diabetes—The experiments described by Murayama suggest that the gratifying result obtained in a severe case of diabetes is ascribed to the giving of six split meals but it is possible that the lower carbohydrate fat ratio in the divided meal period may have also been a factor Absolute proof would not be furnished unless the identical diet both in variety and quantity, should be given the same patient as three meals under the same conditions for a definite time. The justification for this paper is rather the fact that such an intractable glycosuria, withstanding many efforts at desugarization, disappeared with the new divided diet

Anemia on Deficiency Diets—Happ asserts that well balanced diets deficient in iron, do not produce anemia in the rat in the first generation nor do diets consisting solely of cow's milk or milk and bread. Slight anemia may occur in rats of the second generation on these diets. Diets deficient in fat soluble A or water soluble B, although they cause severe nutritional disturbances do not produce anemia in the rat. Diets so deficient in water soluble B as to produce polyneuritis diminish leukopoietic activity and cause a severe leukopenia with a shift to the right in the Arneth formula. Diets low in an organic substance contained especially in cod liver oil with a low calcium but high phosphorus content which produce rickets-like changes in the rat, may also produce anemia provided the animal is kept for a long period on the diet. Animals of the second generation on this diet may also become anemic. This anemia is associated with evidences of increased hematopoietic activity. There is often an enlargement of the spleen. This condition resembles the anemias seen in association with rickets in human beings. A diet low in the organic substance contained in cod liver oil and low in phosphorus with a normal calcium content, a diet that produces severe rickets with great uniformity, does not produce anemia.

Significance of Influenza Bacilli—The main results of Bloomfield's work may be summarized as follows. In the first place it appears that the general incidence of influenza bacilli in the throats of healthy people has declined greatly since the time of the pandemic, the present figure being comparable to that which existed before the wave of influenza in 1918. Furthermore, there seems to be no striking relationship to the season of the year or to the prevalence of minor respiratory infections. An outstanding feature of the carrier state in the persons observed was its usual relatively brief duration and the absence of evidence in the case of healthy people of localization of influenza bacilli in a localized area of diseased tissue such as the tonsil.

Intercolumnar Tubercle in Third Ventricle—A structure in the anterior wall of the third ventricle of the mammalian brain is described by Putnam which appears to be analogous in many ways with the well known areae postremae of the fourth ventricle. It is a small prominence up to one millimeter in diameter situated between the columns of the fornix, at the level of the upper border of the foramina of Monro, below the juncture of the two lateral choroid plexuses. It is composed of a peculiar loose neuroglia tissue, containing many coarse capillaries, and covered by low ependyma. In the human brain it contains small nerve cells. The adventitia of the capillaries takes up trypan blue and other vital dyes intra vitam. No function can at present be assigned to it. The name intercolumnar tubercle is suggested for this structure.

Pseudomyxoma Peritonei—In the male Novak says pseudomyxoma peritonei nearly always occurs from the rupture of a gelatinous cyst of the appendix. In rare cases it may possibly arise elsewhere e. g. in the retroperitoneal tissues. In the female this condition may be due either to ovarian or to appendiceal disease. Sometimes both ovary and appendix are affected, and it may be difficult to say which is responsible for the peritoneal involvement. In such cases the chemical nature of the secretion may be valuable evidence.

Histamin Not an Inflammatory Agent.—A number of experiments were performed by Bloom to determine the inflammatory inciting and chemotactic properties of histamin. In none of these experiments did histamin produce an inflammatory reaction more marked than that caused by the control experiments. Histamin is indifferent with respect to chemotaxis in vivo and in vitro.

Treatment of Nonencapsulated Brain Tumors—Gliomas comprise probably 80 per cent of brain tumors, they are never encapsulated, some are circumscribed, others infiltrating. The fact that they invariably recurred has rendered operative procedures apparently hopeless. In recent work, however Dandy and his associates have made trial of careful resection en masse of a zone of normal brain tissue with the tumor in the center. They have removed an entire right or left frontal lobe without any observable mental or other after effect. Whole right temporal or right occipital lobes have been removed with only a contralateral homonomous hemianopsia. In two instances, it has been necessary to resect the right temporal lobe and the occipital lobes. Virtually complete resection of one or two lobes of the cerebral hemispheres has been done in about ten instances but partial resection of a lobe with the tumor is frequently all that is necessary. The exact amount of brain tissue which must be removed depends on the position, size and character of the tumor. Partial or even complete resection of lobes of the brain entails very little operative risk. The two largest resections were done when the patients were unconscious and complete recovery followed. Similarly, glioma of the cerebellum can be removed by resecting large portions of the cerebellum. Three times the entire vermis was removed and no symptoms have followed. Two boys 10 years old, are well and working four years after removal of the tumor together with all of the vermis and about half of each lateral lobe of the cerebellum.

Effect of Drugs on Blood Sugar—Atkinson and Ets found that the blood sugar content during ether administration also the hydrogen ion value, is raised and the carbon dioxid capacity of the blood plasma decreased The cause of the rise in the sugar may be related to (*a*) the increase in the hydrogen ion which corresponds to a decrease in the *ph*, and (*b*) the decrease in the carbon dioxid capacity of the blood plasma The fat decreased during the ether narcosis and then showed an after rise above normal The cholesterol and lecithin change very little

Creatin and Creatinin Metabolism—Any theory of creatin and creatinin metabolism, Behre and Benedict hold, must take into account the fact that creatin circulating in the blood appears to be essentially a waste product The view proposed by them attempts to do this, and is the only view so far put forward which takes account of the increased blood creatin after impaired kidney function

Histamin in Obstructed Bowel—Histamin was found by Gerard in the contents of isolated closed loops of the large or small intestine The amount varied in different samples, from 2 to 3 mg of histamin dihydrochlorid per 100 c c of fluid being a fair minimum average A combined histamin derivative is also present in obstruction fluid Evidence is presented that this is of peptid nature The sterile secretion of jejunum contains no histamin Sterile mucosa of the jejunum contains histamin, as does the mucosa of closed loops of the jejunum Histidin is present in loop fluid and mucosa Histamin is carried down in heat and acid coagula of loop fluid, and small amounts may be absorbed in the alcohol precipitate from loop fluid

Calcium and Phosphorus in Vegetables—Data are presented by Blatherwick and Long, which indicate that calcium and phosphorus derived from vegetables are capable of meeting the maintenance needs of man

Antiscorbutic Vitamin in Orange Juice—The antiscorbutic vitamin of desiccated orange juice Hart et al found to be soluble in 80 and 95 per cent and absolute ethyl alcohol It is also soluble in methyl alcohol The investigations of others show that it is also soluble in water, but these experiments do not exclude the influence on solubility of the salts inherent in the material extracted This vitamin of desiccated orange juice was found to be insoluble in butyl alcohol as well as in benzene, petroleum ether, acetone, ether, chloroform and ethyl acetate The behavior of this vitamin toward organic solvents and water indicates that it is not of fat or lipin character

Mineral Metabolism of Milch Cow—The results of the investigation reported on by Forbes et al suggest the desirability of building up extensive mineral reserves in growing heifers by liberal allowance of feeds rich in mineral nutrients and also the importance of a dry, resting period of adequate length to permit the restoration of all previous nutrient overdrafts, with liberal feeding during this period

Preparation of Bacillus Acidophilus Milk — Eggston and Norman claim to have produced a milk that is white in color, of a nonlumpy consistency, with practically no odor and in which they can regulate the fat content to suit the requirements of the patient The milk can also be made with an acid or slightly sweetish taste This can be done without altering the bacterial count The white acidophilus milk is prepared in the following way One pint of tap water is placed in a liter flask If one wishes a sweet tasting milk, a heaping tablespoonful of lactose is added to the water which is then autoclaved for twenty minutes under twenty-five pounds pressure The water is cooled and a pound tin of unsweetened evaporated milk is added to the flask, observing sterility The mixture is inoculated with 10 c c of a stock culture of Bacillus acidophilus under aseptic technic, shaken and incubated for twenty-four hours at 99 F The curd formed will be soft, white and slightly separated from the whey at the top The flask is shaken to break the curd, refrigerated, and the milk is ready for use The acidity of the milk is controlled by the incubation period—the longer it incubates the more acid it becomes The fat content may also be regulated by varying the amount of water or milk

Case of Mercuric Chlorid Poisoning A Ellsworth Warren —p 629
Prevention of Mental Disease A Gordon Philadelphia —p 630

Mortality of Resection of Cancer of Colon —The mortality rate for resection of the large intestine for carcinoma, which has ranged from 15 to 45 per cent, Crile shows has been reduced to 2 plus per cent and cases hitherto considered inoperable have been brought within the range of operability

Value of Wassermann Test —A correlative review made by Haythorn of the clinical and laboratory records of 6387 Wassermann tests made under as nearly constant conditions as possible, indicates that the partially positive or atypically test has a place of distinct value in the diagnosis and the control of the treatment of syphilis

Urea Concentration Test for Kidney Function —Weiss regards the urea concentration test as a simple and fairly reliable method of determining the efficiency of the kidney, but notwithstanding certain theoretic advantages which it possesses over other methods, practically it is not ideal and should, therefore, be considered a useful adjunct test to be employed in conjunction with other methods the whole being weighed with the clinical data in an evaluation of a case of renal disease

Moss Agate Tracheal Sputum in Chronic Tracheitis —Moss agate tracheal sputum is the name given by Jackson to a characteristic secretion seen in cases of chronic tracheitis The characteristics are (*a*) A gray color (*b*) A degree of opalescent translucency (*c*) A dark mottling which gives to the sputum an appearance like a gray moss agate stone (*d*) A more or less globular form of sputum mass (*e*) A tough tenacious consistency sometimes gelatinous (*f*) A tendency, at times, to be projected from the mouth in coughing (*g*) A tendency to accumulate in the larynx, whence it is removed by cough or by semicough (*h*) When it accumulates on the cords it often causes diphonia by creating temporary nodal points (*i*) A scantiness in quantity as compared to the sputum of most bronchial and pulmonary diseases

Circulatory Efficiency in Cardiac Disease —Wolferth asserts that to evaluate the cardiac function, it is necessary to consider how efficiently the circulation performs under the stresses of everyday life as well as special loads The possible effects of disease outside the heart which may influence circulatory function must be weighed It may be misleading to form an opinion of cardiac function based on a single type of test or worse still, on only one of the reactions to such a test In the absence of a satisfactory test, all the available data must be taken into account

Laboratory Methods in the Diagnosis of Chronic Tropical Diarrhea —Gonzalez Martinez describes the characteristics of the causal micro organism, the fixation of complement test and its importance and reliability in differential diagnosis, and the brilliant success of vaccine therapy Few diseases have such a solid basis of established facts microbiologic, experimental serologic and therapeutic, which have been accumulated at the Porto Rico Hygiene and Tropical Medicine Institute by Gonzalez Martinez, C Michel and B K Ashford The causal micro organism has been named *Parasaccharomyces ashfordi*

Endocrine Glands and Tropical Pathology —Garcia de Quevedo remarks that well defined diseases of endocrine origin such as Addison's disease, exophthalmic goiter acromegaly etc are rare in Porto Rico On the other hand, abnormal functioning of endocrine glands is a frequent confusing element in tropical pathology Giantism is rare in Porto Rico but dwarf growth is frequent Among the 17,000 drafted men examined for the World War, very few were over 5 feet 10 inches and many failed to reach the army minimum of 5 feet 4 inches

Diagnosis of Hysteria—Speaking of the treatment of hysteria, Head says If possible, the patient should be removed from the usual surroundings and new influences brought to bear An attempt should be made to switch the dissociated part into the continuity of the patient's mental life Every form of persuasion should be exercised to convince the patient that he is able to carry out the action he is convinced to be impossible Never bully him or accuse him of dishonesty No one is a greater failure than the medical officer who wishes all hysterics could be shot at dawn On the other hand, the firm diplomatist with subtle and demonstrable reasons why the patient can stand, walk, or feel, often produces miraculous cures But it must never be forgotten that in a large number of cases, especially in civil life, removal of hysterical symptoms is only a prelude to the discovery of an anxiety neurosis The causes for the suppressed emotion must be investigated, or the patient may be left in an even worse condition than that in which he was found *Do the patient no harm by antitherapeutic suggestion*, carefully prune conversation, and do not think the diagnosis aloud Avoid such words as "neuritis' Some diagnoses, such as 'floating kidney," are more deadly than the disease Avoid thinking in terms of surgery when dealing with functional neuroses At the same time the most brilliant conversation is useless with an hysteric

Case of Ovarian Cyst J W H Chun —p 45

Trachoma in China—Li says that trachoma is undoubtedly the greatest single cause of the economic losses that are occurring in China today but it is appalling to find that so much apathy exists concerning a disease which has made millions of people blind and several times that many nearly blind

Uniform Medical Nomenclature in China—Yui reports briefly on the work done thus far by the Scientific Terminology Association The association has been working for seven years on terminology with the result that 10 000 terms are fixed It has the selected terms of old or Japanese translations, and modifications are made if necessary Yui insists that China should have a medical literature of her own She cannot indefinitely depend on foreign languages for instruction Medical science, if taught in Chinese, can permeate the whole of China more quickly and with much greater ease, but only the approved terms should be used, hence the importance of adopting a uniform medical nomenclature

Laceration of Cervix Involving Lower Uterine Segment and Fornix. R A. Lennie —p 257
Tay Sachs Disease Symptomatology and Pathology of Three Atypical Cases H W Torrance —p 263
*Herpes and Varicella W M Elliott —p 274
*Unusual Case of Extraperitoneal Abdominal Pregnancy D M Lindsay —p 277

Herpes and Varicella—Out of nine cases of herpes occurring in wards in charge of Elliott, outbreaks of chickenpox followed in five, all within the acknowledged incubation period of the disease, and in none of the outbreaks was any source discoverable—that is to say, no other cases of chickenpox either actual or suspicious, had occurred in the ward and all the patients attacked had been in the ward for a time much over the incubation period In two of the nine cases there appears to be considerable doubt as to the diagnosis of a *septic condition or impetigo* If these two cases are discarded, there emerges the rather striking fact that out of seven occasions on which the patient in a ward developed herpes zoster, unexplainable chickenpox followed in five

Extraperitoneal Abdominal Pregnancy—Lindsay cites the case of a woman of 31, who complained of 'pains back and front and stated that her "waters had broken, Dec. 31, 1919 Inquiry revealed that her menstrual periods were regular and painless and that she had menstruated regularly and normally until June 10, 1919 The breasts were enlarged the nipples pigmented and secretion could readily be expressed The abdomen was prominent the abdominal muscles somewhat taut, and there was a readily palpable mass of the size and consistence and in the position of a four months' pregnant uterus Fetal parts or movements were not palpable and the patient herself had not been conscious of fetal movement Careful auscultation failed to discover sounds of a fetal heart Pieces of decidua were passed and fever developed, irregular, but reaching 104 F February 13 an incision was made in the convex right fornix, releasing a great quantity of foul smelling, brownish, pus streaked fluid Much green gray membranous debris fetal skeletal parts and decomposing fetal soft parts were removed piecemeal with ovum forceps Calculated from the size of *the femora and humeri Lindsay says the fetus must* have been between the fifth and sixth month of intra-uterine life The pus contained streptococci and coliform bacilli also a gram-positive bacillus showing terminal spore formation March 22 a further operation was deemed necessary The urethra was dilated, and more osseous remains were removed from the bladder Despite all efforts at stimulation the patient died There was in this case absence of a history of acute abdominal pain, even of discomfort or of hemorrhage Lindsay says the formation of the vesical fistula prior to operative intervention seems new

*Etiology of Beriberi K Ohomori M D Y Ohhashi H Nakamichi M Hara and T Ota —p 128
Experimental Polished Rice Diseases in Human K Taguchi S Hiraishi and I Kwa —p 133

Etiology of Beriberi —Ohomori and his associates performed experiments which show that beriberi is produced in healthy men when they take food deficient in vitamin B Thus it is clearly established that beriberi is avitaminosis Therefore without changing the diet, it may be cured by supplying vitamin B

Beriberi and Human Polished Rice Disease —The beriberi and human polished rice diseases, according to Taguchi et al, are not absolutely the same or identical diseases But from the clinical side the human polished rice disease cannot be distinguished from beriberi If polished rice disease can be considered as avitaminosis the human experiments of polished rice disease give a considerable weight to the theory that beriberi is due to lack of vitamin B

Journal of Neurology and Psychopathology, Bristol

May 1922 2 No 9

*Causalgia and Allied Painful Conditions Due to Lesions of Peripheral Nerves H S Carter —p 1
Inhibition and Excitation in Central Nervous System T G Brown —p 39
*Psychopathology and Theory of Psychopathic (Germinal) Inheritance I D Suttie —p 42
*Treatment of Spastic Paralysis R G Gordon —p 47
Erythromelalgia Causalgia and Allied Condition S Kelly —p 55

Etiology of Causalgia —The fundamental lesion in causalgia and allied conditions, Carter says, is one of intraneural and perineural sclerosis and the irritation thus set up of fibers at the site of injury to the nerve causes perverted afferent impulses to be sent back to the cord, and possibly further to the subcortical and cortical centers and thence efferent responses of vasodilator secretory and trophic natures are reflected to the peripheral distribution of the nerve where reaction on the end organs and sensory corpuscles in this area is interpreted as pain The reason why lesions of this type of the median nerve and internal popliteal fibers produce a true causalgia in some cases, pain of less severity in others, and in the remainder nothing but the discomfort of partial sensory loss, is difficult to answer It is improbable that inflammatory reaction to different groups of organisms provides a solution It hardly seems possible that irritation of a special group of fibers is the cause for causalgia is rare and it is not within the range of probability that such fibers should be so seldom involved The most that can be said is that there is some peculiarity in the trauma of the nerve in these few cases, which causes disturbance of those cells in the brain whose function it is to interpret pain By resection of the irritated and sclerosed portion of nerve the source of the perverted impulses is removed and the pain vanishes and by restoring the continuity of the nerve the path for normal impulses is remade and gradually recovers its conductivity as the nerve regenerates Details of twenty-four cases are given

Theory of Psychopathic Inheritance —Suttie attempts to show that the neuropathologic theory of mental disease is associated with the hypothesis of its hereditary transmission He thinks even that the two lend each other moral' as well as logical support He also indicates that the crucial test of the ultimate validity of psychopathologic interpretation is its ability to account for high familial incidence of the disease form to which it is applied To hazard a tentative judgment on these lines while presuming an agreement on the evidence it might be said that as certain mental syndromes have no typical or integrated psychic aspect but have, on the other hand a demonstrably organic basis, it must be inferred that any hereditary relation is physical and mutatis mutandis where no neural lesion or abnormality is discoverable Thus mental defect is heritable, the psychoses are questionably so with the exception of paranoia, which with the minor and anomalous neuroses are probably acquired

Treatment of Spastic Paralysis —In cases of spastic paraplegia muscles are already hypertonic and further stimulation by electricity or massage, as usually given, will increase their tone and make matters worse A very important point in the treatment of spastic cases according to Gordon is, by the use of proper splints to prevent the weaker muscles being stretched and rendered atonic Contractures are the result of neglecting to apply a light celluloid splint or a leather gaiter So far as active treatment is concerned, it is essential to attempt to induce relaxation of the hypertonic muscles and encourage the action of their opponents

Alimentary Toxemia in Nervous Disorders —To prevent the nervous complications of this condition and to avoid infection from the alimentary tract, Thompson states that it is essential first of all to attend to the hygiene of the mouth and associated cavities Regular daily evacuation of the bowels is essential in the majority of people The relation of food ingested to alimentary toxemia is very important The ingestion of large quantities of meat tends to produce excessive fermentation in the intestine The ingestion of carbohydrates, especially sugar favors certain forms of intestinal putrefaction It is probable that diminution of the total bulk of the food is of most value in reducing alimentary toxemia Most people eat far too much and might with advantage make a very considerable diminution in the total amount of food eaten The preparation of food is also most important, all salads and uncooked vegetables should be washed carefully and prepared before being eaten. Milk is a potent source of infection of the alimentary tract, and the utmost endeavor should be made to obtain a pure milk sup-

ply The methods which have been adopted of modifying bacterial contents of the intestine are important The giving of vaccines prepared from the *Bacillus coli* and streptococcus normally found in the feces is strongly condemned If abnormal organisms are found in the feces and definite signs of intestinal poisoning are present, giving a vaccine made from such abnormal microbes is occasionally followed by good results The introduction of lactic acid bacilli into the intestine with a view to diminishing intestinal fermentation has had a long and persistent trial with results not as successful as was at one time hoped Intestinal disinfectants are certainly of use in many cases These may be divided into mercurial preparations, salicylate preparations, and phenol derivatives Of the mercurial preparations, calomel is the most effective, and is best given in small doses of 1/10 grain Of the salicylate preparations, sodium salicylate and phenyl salicylate have proved of value The taking of copious amounts of fluids also seems to have a good effect in cases of alimentary toxemia Lavage of the large intestine has also been of considerable help

Syphilis in General Practice — Power discusses mistakes due to (1) the unlikelihood of infection owing to the social position of the patient or the unusual mode of infection, (2) prolonged latency of symptoms generally in connection with inherited syphilis, as in cases where the patient has no stigmata, has married, and has had healthy children, or, in the acquired disease, where very many years have elapsed since the patient had any signs Under both conditions increasing age or slight injury appears to be the determining cause of the syphilitic manifestation (3) The modifying effect of syphilis on other forms of infective inflammation, whether it be tuberculous, phagedenic, streptococcal or staphylococcal The conclusion arrived at is that syphilis affects a sufficiently large number of the population to make it worth while to bear in mind the possibility of a spirochetal factor in many of the obscure and chronic inflammations which do not respond to the ordinary methods of treatment

Basal Metabolism in Pregnancy — Wilson and Bourne point out that the basal metabolic rate is in the majority of pregnant women, but not in all, raised above that normally found in the nonpregnant woman The basal metabolic rate of different pregnant women at corresponding periods of gestation varies considerably, but they have not found it possible to trace any relation between these variations in the rate and the clinical condition of the mother In some patients, probably the majority, the rise in the basal metabolic rate disappears after delivery, but in a certain number of cases the high rate of pregnancy does not subside after the puerperium, but abnormally persists The suggestion is put forward that in some of the latter cases the excessive thyroid secretion gives rise to a menorrhagia without pelvic signs Additional evidence that a high basal metabolic rate is associated with certain forms of menorrhagia is furnished by a group of cases to which the label functional menorrhagia is attached, to draw attention to the absence of any demonstrable pelvic abnormality The cases comprising this group are resistant to all ordinary medicinal and operative measures, but respond readily when the thyroid gland is exposed to roentgen rays The disappearance of pelvic symptoms is coincident with a fall to the normal of the basal metabolic rate

Prognosis in Diabetes Mellitus — Before treatment is begun a valuable index of the gravity of the disease, Lyon states, is the degree and rapidity of body-wasting that has taken place For practical purposes the best guide to the severity of the condition is the total amount of glucose lost each day in the urine, but this sign, like nearly all others, fails to distinguish between temporary and permanent damage Laboratory tests show that in cases of diabetes a degree of hyperglycemia may still be present even when sugar no longer appears in the urine Mere estimations of the gravity of the disease when the patient is first seen give no sure guide to the future, since some cases, apparently severe, do much better than others whose signs are less marked It is therefore recommended that no definite prognosis be given until the character of the patient's response to treatment has been studied

Subclavian Aneurysm with Cervical Rib — The aneurysm in Moore's case sprang from the front of the artery and not from the part in contact with the rib The presence of a normal radial pulse seemed to indicate that there was no compression of the artery It turned out to be a saccular diverticulum of the size of a cherry, springing from the front of the third part of the artery—itself apparently normal in other respects The wall was thin and the sac could be emptied by compressing it A kangaroo-tendon ligature was placed on either side of the sac The operation was straight forward throughout and almost bloodless Next day the arm was normal except for absence of the radial pulse The circulation differed in no other respect from that of the opposite side and all movements were unimpaired There was a little surgical emphysema of the right chest and face, but none of the left side, and no clinical signs of pneumothorax Recovery was uneventful The radial pulse began to reappear on the fourth day, and the aneurysm could be felt but no longer seen, as a firm nonpulsating mass

Focal Tenderness in Gastric Ulcer — By palpating with one finger along the whole of the lesser curvature from a point nearly as high as the cardia, starting from the infrachondral margin down as far as the pylorus, a test is applied in the roentgen ray diagnosis of gastric ulcer which, in Vilvandre's experience is of great value He terms it focal tenderness Palpation similarly applied along other points of the small curvature elicits no response The more intelligent the patient, the more rapid and definite the response

*Diverticulum of Esophagus R Bensaude R Gregoire and G Guenaux —p 145

*Tests for Occult Hemorrhage L Pron —p 204

Diverticulum of Esophagus — This profusely illustrated study of diverticuli at the entrance to the esophagus is based on six operative cases While the diverticulum is forming, some slight disturbance in swallowing is usually noted, and signs of irritation in the pharynx, a tickling and dryness, profuse flow of saliva, the hawking up of thick mucus, frequent spasmodic coughing, and the sensation of a foreign body arrested in the throat Nearly all these diverticulum patients had been long taking treatment for the throat, without the least benefit In a few, the onset of disturbance was sudden, after some trauma to the throat Radioscopy shows the recess its filling up from above, the smooth oval outline, and the way in which it follows the movements of swallowing He prefers to draw the tip of the diverticulum up into the incision made at the point of greatest protrusion, and resect with the thermocautery, between two clamps, suturing at once In 109 cases, with all the operative treatment at one sitting, there were twelve deaths, in three there had been septic cellulitis Suppuration occurred in twenty three cases but these complications are growing constantly rarer The esophagus gives a solid suture, and fluid food can be allowed the fourth or fifth day or even earlier Gross allowed it the next day, Jacobs the second day, and Taylor the fourth

Test for Occult Hemorrhage in the Digestive Tract — Pron concludes from his comparative tests of thirteen different methods that only the Boas chloral-alcohol-guaiac method and the modified Adler method are reliable and sufficiently sensitive The Snapper spectroscopic test is sensitive and specific but is only a laboratory method Boas' test is made with 2 c c of a 70 per cent alcoholic solution of chloral, plus 10 drops of acetic acid, the whole agitated several times and allowed to stand for five minutes The mixture is then poured into a dry glass containing a pinch of freshly and finely pulverized guaiac resin To this is added 20 drops of 3 per cent hydrogen peroxid or a pinch of barium peroxid The modified Adler method is to add a pinch of benzidin to a few cubic centimeters of acetic acid, without heating, and then add the hydrogen peroxid By thus preparing the benzidin solution fresh each time, and diluting well, the reaction is reliable

*Infectious Diseases in 1922 Dopter —p 453
*Antityphoid Vaccination by the Mouth Besredka —p 460
Infectious Diseases in Russia in Recent Years Dopter —p 463
*Intestinal Spirochetosis in Dysentery V de Lavergne —p 467
*Fatal Mumps Reverchon Worms and Delater —p 471
*Treatment of Influenza D Simici —p 474
Disease in Celluloid Workers Heim Agasse Lafont and Feil —p 477

Infectious Diseases in 1922—Dopter says that great progress has been realized, since his last annual review, by the practical application of some of the lessons learned in the World War Epidemic encephalitis seems to be losing its epidemic character Levaditi's finding of the virus on the epithelial cells in the saliva suggests that it may be a parasite of these elements Further progress is the apparent identity of the virus of herpes of the cornea and lips with the virus of epidemic encephalitis, the only difference to be detected in rabbits was the lesser degree of virulence Levaditi's research also sustains the assumption of healthy carriers The virus may have an affinity for the epithelial cells but may acquire periodically an affinity for the central nervous system—the difference seems to be only in the degree of virulence of this *ultravirus encephalitogene* When it acquires the affinity for nerve tissue, then we have an epidemic of encephalitis Others dispute these conclusions saying that the virus of herpes does not induce immunity for encephalitis and vice versa In treatment of the complications of gonorrhea, intra-articular injection of gonococcus antiserum has proved far more effectual than the subcutaneous route Sacquepee recently reported a case of gonococcus septicemia persisting for months until cured by four intravenous injections of the specific serum

Typhoid and Paratyphoid Vaccine by the Mouth—Besredka emphasizes the importance of following in vaccination the route taken by the infection in its invasion This is the reason why guinea-pigs can be successfully vaccinated against anthrax by introducing the vaccine directly into the skin, while intraperitoneal vaccination is always disastrous With dysentery typhoid and cholera the mouth is the route of invasion and vaccination should be by the mouth likewise An experiment in this line has just been made on a large scale in northern France by Vaillant, in a region where typhoid is endemic The populace were persuaded to take a pill of bile and a tablet containing a mixture of heat-killed typhoid and paratyphoid bacilli, before breakfast on three successive mornings, children under 7 took it for only two mornings A total of 1 236 of the inhabitants were thus vaccinated out of a total of 2 000 Among the unvaccinated 7 7 per cent contracted typhoid and 2 3 per cent of the 173 who had been vaccinated by the subcutaneous route Of the 1 236 who had taken the *vaccin bilie* by the mouth, only 0 17 per cent developed the disease The results were thus highly encouraging there were no by-effects except slight colic and headache in a few cases, never enough to interfere with business or appetite The resulting immunization is at least equal to that realized by the subcutaneous route This immunization being strictly local that is intestinal does not require the cooperation of any other organ Hence a lesion in the kidneys liver lungs or elsewhere does not interfere with this form of vaccination although it might contraindicate subcutaneous vaccination

Intestinal Spirochetosis with Dysentery—The symbiosis of fusiform bacilli and spirochetes which is found in Vincent's angina has been discovered in the rectum and colon in cases of dysentery and explains many puzzling pathologic conditions

Pathologic Anatomy of Mumps—This article was reviewed in the Paris Letter

Treatment of Influenza—Simici writes from Bucharest to call attention to the encouraging results he has realized in treatment of influenza by subcutaneous injection of convalescents blood

*The Barranikow Dohle Corpuscles H Accoyer —p 401

The Barranikow-Dohle Bodies in the Leukocytes—Accoyer reports on these bodies in 5 cases of scarlet fever, in 2 of measles, 3 of erysipelas, 3 of tonsillitis, 5 of diphtheria and one each of malaria, mumps and typhoid, besides a number of other cases after defervescence and late into convalescence These inclusions were most numerous the more pathologic the condition, regardless of the nature of the infection He compares the theories in regard to their origin

May 13 1922 **30**, No 38

*Intrathoracic Operations. P Duval —p 409
Calcium Salts in Asystolia D Danielopolu et al —p 413

Unilateral Intrathoracic Operations—Duval insists that unilateral surgical pneumothorax is harmless In dogs, there is an open communication between the pleurae, and hence pneumothorax on one side spreads at once to the other side, so both lungs have to collapse But even in dogs, if the opening into the thorax is closed, the dyspnea subsides, and the dog survives The pleurae do not communicate in man or in the rabbit and calf The pneumothorax on one side did not spread to the other side in his experiments on rabbits and calves Hence, he says, Graham's conclusions from research on dogs are erroneous they do not apply to man With surgical pneumothorax, the lung collapses completely and there is no respiration, the air is quiet not flowing in and out, and the pneumothorax causes no disturbance All the various measures applied to relieve dyspnea with pneumothorax aim merely to arrest this inflow and outflow of air The most effectual is to close the opening in the chest wall, and thus put an end to the pleural ventilation, or else to make the opening still larger and thus insure the total collapse of the lung In two cases the dyspnea subsided when he made the opening larger, and pressed down on the lung with hot compresses to expel all the residual air Differential pressure procedures, etc, are superfluous, all that is needed is to make the opening into the chest large, and immobilize the walls with a retractor which stretches that side of the diaphragm, making sure that all the residual air is squeezed out of the collapsed lung The surgeons can then operate with confidence that there will be no modification of the heart or respiration rhythm, the collapsed lung safely tucked out of the way He makes a point of aspirating out all the air in the pleura the last thing before completing the suture. The roentgenologist watches as this is being cautiously done, and notifies the surgeon the moment the entire lung expands to reach the chest wall The results have been most gratifying in his experience with over 100 intrathoracic operations of the kind, many of them for extensive war wounds All recovered but one man who was suffocated by pus, and another with cancer of the esophagus

*Radiotherapy of Pituitary Tumors F Terrien —p 429
Intravenous Quinin Treatment of Malaria Genevrier —p 431
*Cardiac Thrombostasis R Lutembacher —p 432
*The Anilin Dyes in Surgery L. Chemisse.—p 435

Radiotherapy of Pituitary Tumors—A combination of organotherapy, mercurial treatment and the roentgen rays has given excellent results in nearly all the cases of pituitary tumors in which it has been tried Terrien adds that the effect was particularly striking on the trophic disturbances from the tumor, and above all on the headache and impairment of vision In 148 cases of pituitary tumor with visual disturbances on record, there was blindness in 34 but choked disk only in 15 In 10 cases treated with radiotherapy the improvement in the visual field is evident from the charts given as also in Carlotti's 4 cases In some of these cases vision was regained after several months of blindness Beclere irradiates the pituitary through mouth, brow and temples where the bone is thinnest, using 5 H units at each sitting In all his cases the action was durable One patient has had no recurrence during nine years to date In one of the cases the radiotherapy seemed to reduce the visual field, hence extreme caution is necessary The effect is most pronounced with disturbances of mechanical origin

Cardiac Thrombostasis—Lutembacher describes the clinical picture induced by thrombi in the heart, too large to pass into the vessels Even at necropsy the cause of the sudden death may not be suspected unless the heart is opened up

The Anilin Dyes in Surgery—Chemisse concludes his review of recent literature on this subject with the statement that the anilin dyes seem to act only on staphylococci and streptococci

*Baldness in the Twenties R Sabouraud —p 465
*Silent Cavities in Lungs R Burnand and R Carrard —p 467

Baldness in the Twenties—Sabouraud remarks that many insects and birds, at the age corresponding to the twenties in men, develop some ornamental feature, a nuptial robe, while

man may lose his hair at this time and thus be deprived of part of his comeliness 'This is illogical and unnatural, and the reason for it is a mystery that will probably baffle several generations yet" No treatment of seborrhea and of seborrheic alopecia has given any appreciable results to date Local measures may retard the baldness but they never cure A down may grow and encourage the patient, but the hairs are atrophic and do not last The best local treatment of these grave seborrheas is carbon sulphid, in spite of the drawbacks of its odor, its inflammability and the smarting it induces It is the only treatment, he says, which in a few weeks seems to arrest this premature baldness of young men and the seborrhea directly responsible for it His formula is 75 c c of acetone, xylene or benzin, 75 c c of carbon tetrachlorid, 150 c c of carbon disulphid and 9 gm of precipitated washed sulphur He suggests the possibility of organotherapy with an extract of the interstitial gland, which seems to have under its control the secondary sexual characteristics But no one has tried it as yet, and we cannot experiment on animals, as seborrheic alopecia is unknown outside of the human species When the baldness seems to follow an illness, the typhoid or other infection has merely hastened the course of the already established alopecia It begins with the genital period, and castration prevents it No tendency to baldness was found in 340 eunuchs examined by his correspondents in Asia In seborrheic alopecia new hairs sprout as soon as the old fall but each new crop is weaker and smaller to final total atrophy Unless a family tendency is known the young men do not apply for treatment until two, five, ten years too late The earlier the seborrheic alopecia begins, the more rapid and severe the course He knows of two brothers who were both bald at 18 When it begins at 16 or 17 it is established at 24, but when it does not begin till 18, the baldness is not complete till 27 or 28 The satyrs on the Greek vases were always young and bald

Silent Tuberculous Cavities—Burnand remarks that tuberculous cavities not inducing appreciable symptoms are nothing new, but he has been amazed to find that 55 per cent of the tuberculous cavities shown up by the roentgen rays had not induced characteristic symptoms In forty-two cases the only possible suggestion of a cavity was what he calls the *obscurite respiratoire d un territoire trouble* In twenty-three others the physical findings indicated merely a focus of softening of the second degree

Neuritis O Veraguth—p 445
*Strophanthin by the Vein H Staub—p 447
*Fat Embolism of the Brain J Tobler—p 452
Testing Vision I Strebel—p 456
*Substitute for Duhrssen's Tampon F Schreiber—p 458

Notes of a Neurologist.—Veraguth describes a case of polyneuritis with both tonic and paretic features, but without incapacitating the man of 40, a Cook's guide In another case a Korsakow psychosis followed an attack of botulism poisoning in a woman with pronounced polyneuritis In another woman, polyneuritis had developed after two operations for recurring mammary cancer The polyneuritis included the fifth, sixth and twelfth cranial nerves In another case, carbon monoxid poisoning had induced the polyneuritis The carbon monoxid had developed from a pile of phonograph records evidently set on fire by the drowsy man's cigar When he regained consciousness, twenty-four hours later he was lying on the floor, his legs paralyzed and also the right facial nerve and shoulder muscles, and he and the room were covered with soot The polyneuritis was intensely painful for six months but it then subsided The case raises anew the old question whether carbon monoxid polyneuritis is of toxic or mechanical origin, from lying so many hours in a cramped position unconscious The gradually increasing paralysis of arms and legs in another man was traced to occupational use of "solvent naphtha" in automobiles

Strophanthin.—Staub gives tracings from a case of severe cardiac asthma kept under control with strophanthin for the two years the man of 52 was under observation The intervals were finally increased to ten or twelve days, and he was able to resume his work as a shoemaker Staub warns that strophanthin has a cumulative action though not so pronounced as digitalis and only half the dose should be given if digitalis has been taken in the preceding two days

Fat Embolism of Brain.—Tobler operated in the case described to relieve the pressure on the brain from unknown cause the fat embolism not having been suspected The man's leg had been fractured, he became unconscious after the fracture had been dressed This free interval before the stupor is instructive The urine and sputum may show fat droplets, but they may be found even without signs of fat embolism Numerous symmetrical punctiform hemorrhages in the skin are characteristic, they appeared from the third day on in six cases on record Headache, trismus and spasms of the limbs have been observed, as also isolated paralysis, vomiting, arrhythmia and fever but are not pathognomonic The fat embolism in this case was not suspected until necropsy, when the peculiar purpura aspect of the brain first suggested it

Aluminum Acetate to Arrest Hemorrhage—Schreiber relates that this drug has never failed in his twenty-five years of practice to arrest hemorrhage from inertia of the uterus at childbirth and has proved its usefulness in many cases of parenchymatous hemorrhage of various organs He uses it in a 2 or 3 per cent solution to arrest obstetric hemorrhages, diluting the official 10 per cent solution, which keeps indefinitely The hemorrhage after tonsillectomy was always arrested at once by rinsing out the nasopharynx with the 10 per cent solution

Bacteriologic Research on Malta Fever E Gerbasi—p 289
*Whooping Cough in the New Born G Milio—p 297
*Tumor in Rhinopharynx D Tanturri—p 302
Urticaria and Ascaridiasis O Pentagna—p 308

Bacteriology of Malta Fever—Gerbasi discusses the biologic and morphologic behavior of the Bruce micrococcus and others resembling it

Whooping Cough in the New-Born—Milio relates that the disease was severe in the two infants 8 and 10 days old, but he tided both safely past the gravest period by an intramuscular injection of 5 c c of ether every second day The paroxysms grew gradually less severe and less frequent He gave a total of six and eight injections No benefit was apparent until after the third injection but then progressive improvement was manifest

Tumor in Nasopharynx of Small Child—Tanturri reports another case of successful extirpation of a tumor in the nasopharynx The cautery loop in a protecting catheter was introduced through the nose (after cocain and epinephrin) It was fitted over the base of the neoplasm the latter having been loosened up with the fingers The electric current was then turned on for electrolysis of the base of the tumor As the mass forming the tumor dropped off, it was seized with

forceps and extracted through the mouth There was no hemorrhage, and there has been no recurrence during the nearly four years to date He has operated in this way in a number of other children, and all with similar success The tumor in this case was a cystic fibroma showing sarcomatous degeneration

Ascaridiasis and Urticaria—The disappearance of the urticaria after a vermifuge apparently explained it as a manifestation of anaphylaxis from the ascaridiasis

*Treatment of Tuberculous Meningitis O Cozzolino—p 433
Chloroma in Child of 3 G Caronia—p 439
*Influence of Protein Therapy on Phagocytosis A Dominici—p 446

Treatment of Tuberculous Meningitis—Cozzolino has been giving a trial to Bier's method of passive hyperemia in treatment of tuberculous meningitis in three children 4, 7 and 8 years old He was inspired to do this by the report of two cases cured by this means, plus lumbar puncture, published in the *Munchener medizinische Wochenschrift* in 1913, p 1430 No benefit was apparent in Cozzolino's cases, nor in Squarti's eight cases (1916)

Influence on Phagocytosis of Protein Therapy—Dominici reports considerable research on guinea-pigs which demonstrated that phagocytosis was remarkably stimulated and the inoculated bacteria rapidly disappeared from the peritoneal effusion under the influence of parenteral injection of a protein, either whole milk or peptone or a vaccine The similar effect induced by all these different proteins—the striking activation of phagocytosis that follows at once the parenteral injection of a small amount—suggests a uniform mechanism A large dose has a paralyzing effect She noted a specific action in addition from antityphoid vaccine after inoculation with typhoid bacilli Even twice the lethal dose was thus conquered In experiments with the other proteins the bacteria injected were always below the lethal dose

*Epidemic Lymphadenitis V Vanni—p 438
*Malformations in Sexual Perverts M Carrara—p 440
Pathology of the Patella E Arevoli—p 443

Optic Test for Total Amount of Blood—Moscati determines the polarizing action of the blood before and five minutes after injection into the blood stream of a given solution of glucose His experiments in this line on dogs with experimental nephritis confirmed the assumption that there is actually a permanent hydremic plethora from an increase in the total amount of the blood, and especially of the plasma, in experimental nephritis with much albuminuria

Epidemic Lymphadenitis—Vanni was sent to a remote part of the province of Rome to study an epidemic illness which began with sudden pain in one inguinal region followed by torpid ulceration of the local glands, each ulcerating separately Fever was slight and irregular, and the whole healed in from four to six months, the ulcerations leaving pits It was highly contagious, and affected both sexes and all ages A minute micrococcus was shown up by the Ziehl and Giemsa stains in the puncture fluid from the glands Guinea-pigs injected with this fluid or with cultures of the micrococcus mostly died in a few days, and the liver, kidneys and suprarenals were found much enlarged, the spleen very small

Local Malformations in Sexual Perverts—Carrara is director of the Istituto di Medicina Legale at Turin He writes to protest against the traditional assumption that, because a person is suspected of being a sexual pervert any abnormal conditions found in the sexual organs or anus are necessarily the result of "sexual delinquency" He declares on the contrary that the abnormal conditions may have been primary, and they may have been a factor in the sexual psychopathy His text is a recent medicolegal case in which a daughter accused her father—a man prominent in social and business life—of incest rape, and presented a medical certificate to the effect that the vagina and anus were so large and smooth that they proved multiple sexual relations The physician who signed the certificate confirmed it in the witness stand, and the court was more than disposed to accept his view

*Spinal Fluid in Neurosyphilis A Terzani—p 97 Conc n No 10 p 109

The Spinal Fluid in Disease of the Nervous System—Terzani describes and criticizes the various reactions that can be induced in the cerebrospinal fluid with disease of the nervous system, especially in neurosyphilis He gives an instructive table of the findings with eleven different parallel tests in 36 cases, including 3 of tabes and 3 of general paresis He regards Boveri's simple test as very useful Although it is not specific for any special disease, yet it warns of the presence of an organic lesion, and often this is all that we need to know for management of the case He pours along the wall of a test tube containing 1 c c of the cerebrospinal fluid, 0 1 c c of a 1 1,000 solution of potassium permanganate (not 1 c c as often published) A yellow zone forms at the junction of the two fluids or spreads through the whole if they are mixed The intensity of the reaction is indicated by the promptness with which the tint changes, from two to six minutes is the accepted range for a positive response In his series the strongest reaction was obtained with epidemic and tuberculous meningitis (half a minute to two minutes), in general paresis (one to three minutes), in acute poliomyelitis (three to four), and epilepsy (four minutes) The differential count of the cells in the sediment is also important In one of the cases of tabes the Boveri reaction was pronounced although the Wassermann was negative

*Lesions from Medicolegal Point of View A Barreras y Fernandez—p 14
Medical Officers R de Castro y Bachiller—p 40

Lesions from Medicolegal Point of View—Barreras emphasizes that the prognosis from the medicolegal standpoint is different from that of the pathologist. The length of the resulting disability, the physical defect left and the deformity—all have their bearing on the medicolegal estimation of the case, as he shows by his classification and examples. The definition of deformity or disfigurement its degree etc. and the age and sex of the injured, the motive etc., all have to be taken into account, as he explains.

Melanic Epithelioma of the Conjunctiva. C. Jimenez Lopez, V. Ribon and V. Leon Chavarria.—p. 609

Pregnancy in Heart Disease—The young woman reached term without grave disturbance from the congenital mitral stenosis which before the pregnancy had always been well compensated. Labor brought severe asystolic arrhythmia and cyanosis. After fourteen hours of ineffectual labor under spinal anesthesia the cervix was dilated with the fingers, the perineum incised as the head presented, while pressure was applied to the abdomen and the child was extracted with forceps. The patient was kept in a semiseated position as much of the time as possible. Compensation was soon restored under tonics, restriction to milk and cupping. The child is developing normally.

Fever with Hemoptysis—Gorriti has noticed at the national sanatorium for the tuberculous in his charge that hemoptysis sometimes occurs in several of the patients at once during the same day or week. This collective appearance of hemoptysis always coincided with a low barometer. Men are affected with hemoptysis far more frequently than women and he reasoned that menstruation serves as a safety valve to ward off hemoptysis. This assumption suggests the advisability of occasional venesection in prophylaxis of hemoptysis in men known to have a tendency to hemorrhage from the lungs. Fever with hemoptysis is not due entirely to the toxic-infectious process, the reabsorption of the extravasated blood may explain a certain proportion of it if not the whole. It is like the fever with a simple fracture.

Primary Thiersch Flaps Over Large Area. O. H. Petersen.—p. 730

Clinical Importance of Accessory Renal Vessels—Petren's own experience and review of the literature have confirmed the probability of there being some abnormal blood vessel in the kidney when there are repeated attacks of pyelitis and no calculi can be detected with the roentgen rays, the ureters can be normally catheterized, and the kidney pelvis is dilated while the urine and micturition seem normal. The suspicion of hydronephrosis from an accessory vessel justifies an exploratory incision at once. Unusually profuse hemorrhage at an operation on the kidney can usually be explained by some supernumerary vessel. In operating on the kidney, he adds, it is well to bear in mind that one kidney in every five has some anomaly in its vessels.

Embolic Gangrene—A similar article by Bull was summarized in these columns March 18, 1922, p. 855. He warns that pains or functional disturbance or both anywhere in the body with any form of heart disease should always suggest embolism. The surgeon is practically powerless if the diagnosis is not made until gangrene is under way.

Mammary Cancers—Feist and Bauer give a retrospective analysis of 128 cases at Prague, and compare their findings with the literature. Over 72.7 per cent. are still cured after three years but only 33.3 per cent. of those with glands affected at the time. Local recurrence was observed in 17 per cent. The outcome was much less favorable in the cell-poor scirrhous tumors than in the cell-rich tumors. About 42 per cent. died from internal metastasis, and twice as many of those with scirrhous tumors as of the solid cell-rich tumors. Only the most extensive excision of the soft parts, especially of the skin and subcutaneous fat tissue, guarantees against local recurrence. In only 31 per cent. of the entire number was the interval from the first discovery of the tumor less than three months. In 72.5 per cent. there was already metastasis in the glands in the axilla, and in 48.4 per cent. the skin was already involved.

Acute Malignant Degenerative Syphilis. A. Pfeiffer.—p. 245
Catalase Content of Blood in Pernicious Anemia. H. Korallus.—p. 252

The Kidneys in Gout and Lead Poisoning—In the 8 cases of chronic lead poisoning and 6 of gout described here there was nothing in the history to indicate that there had ever been an acute hemorrhagic nephritis so the necropsy findings can be ascribed to the lead or the gout. Deposits of urates were found in only 2 cases but the blood vessels showed pronounced changes in both the lead and the gout cases as also the glomeruli, the findings in the tubuli differed materially.

Poliomyelitis During Influenza Epidemic—Hiller reports 10 cases of acute spinal disease during a recent six months, accompanying an epidemic of influenza at Dresden. In 6 cases the clinical picture was that of acute anterior poliomyelitis, in 3 it was more an acute diffuse myelitis and in another case a sudden paralysis of the bladder was the only disturbance. This case was the only one in which recovery has been complete. The paralysis in the others very slowly retrogressed and there are still traces of it. His study of the records has shown an epidemic appearance of disease of the central nervous system during the great influenza epidemics of 1712 and 1889-1890. The connection between infantile spinal paralysis and epidemic encephalitis needs further study. The onset differs in these diseases, the meningitis of the former being scarcely noted with the latter and then is evidently only secondary. In 2 of the cases here described the extensive myelitis had induced the picture of hematomyelia. In a compilation in 1907 of 25 cases of spontaneous hematomyelia, 14 were known to have occurred during or shortly after an epidemic of influenza.

The Muscle Tonus—In this first article of a series Grafe discusses the influence of changes in tonus on the total metabolism with organic nerve disease, tabulating under nineteen headings the various findings in sixteen cases.

Research on Percussion and Auscultation—Martini in this second communication studies the laws and interpretation of tympanitic and nontympanitic resonance

Primary Oliguria—Veil explains how primary oliguria can occur, the exact opposite of diabetes insipidus It may be from organic or functional disturbance in the autonomic nervous system, a vegetative neurosis in the edema line Some cases of different types are described In treatment, calcium and iodin must be considered Iodin is most effectual in daily doses of not more than 0 25 mg Ovarian extract may be useful to combat a dropsical tendency

Reaction of Diabetics to Epinephrin—The findings are recorded in twelve diabetics in regard to the glycemia after a test injection of epinephrin the vasomotor reaction, glycosuria, acidity of the urine, ketonuria and the carbon dioxid tension in the alveolar air

Acute Malignant Syphilis—The acute degeneration affected the liver, kidneys and spinal cord in the three cases described The syphilis was of twenty years standing in one case, and the clinical picture with the acute degeneration of the liver was of the acute yellow atrophy type

Lawn-Tennis Leg—In the midst of a tennis game, a player suddenly stops short on feeling a sharp pain in the calf or farther down on the leg Kuttner states A muscle or a tendon (the Achilles tendon) has been torn Usually the player is able to limp off the court, but sometimes has to be carried off A roentgenogram will confirm the usually certain diagnosis, and will reveal the details in regard to the site and extent of the laceration, as the tendon casts a distinct shadow on the roentgen plate The roentgenogram is also useful in following the healing process in the tendon or muscle Formerly such injuries were treated with splints or plaster bandages or even surgical therapy, with operative exposure of the injury and suture The results were not good, or at least recovery was delayed as is shown by Dr Fanes own experience, since it was nineteen months before he could walk without embarrassment The only correct treatment is that which lays stress on the rapid restoration of function, does not confine the patient to bed, and induces him to begin walking at once In mild cases, with a partial rupture of a muscle, this causes no difficulty With the aid of a cane the patient should at once make an attempt to walk, which will be painful at first, but after two or three days it will be easier, and after a week a normal gait can usually be reached In the mild cases bandages are unnecessary and massage is superfluous For nervous patients, if the pain is severe, a bandage may be used For three or four weeks, all violent exercise, including tennis, should be avoided, especially in older persons, as the lacerated muscle or tendon will otherwise break down again Even in severe cases—total rupture of the Achilles tendon—walking should be begun at once but here, since the pain is great and the foot is weak, the treatment introduced by *Hood* in England should be instituted The patient reclines on a sofa and the injured leg is kept in an elevated position This suffices to check the hemorrhage to bring down the swelling and ease the tension The patient is admonished to walk more and more each day In the severe cases the bandages may be renewed until the patient feels that he can dispense with them The prognosis is excellent even when the Achilles tendon is severed, but partial rupture of the muscle heals much more rapidly though pain is in the muscle may be felt for several months

Carbohydrate Metabolism of Liver Patients—Hetenyi states, after research in more than a hundred cases of various forms of liver disease, that he was unable to find that the blood sugar values fasting were appreciably affected From his experiments he found that lesions of the liver may affect the blood sugar in two ways By loss of functioning parenchyma, sugar formation in the liver is lessened, and obstruction of the bile ducts impairs glycogen fixation on the part of the liver When we apply the role of these factors to human pathology, we can ascribe to the first factor only a limited importance The effect of the second factor was shown in the high blood sugar values in patients with icterus

Desquamation of the Urinary Tract in Scarlet Fever—Gonnella's investigations lead him to believe that ordinarily there is a desquamation of the urinary tract in scarlet fever analogous to the desquamation of the epidermis

Quinidin-Digitalis Treatment of Auricular Fibrillation—Starkenstein states that the use of quinin and digitalis combined is justified if in connection with prolonged digitalis medication it is necessary to counteract possible cumulative effects or other dangers from intoxication, and more especially if the heart is already showing toxic symptoms, in which case the toxic remedy is omitted and the other employed as 'antagonist" In certain cases the combination may be valuable for the strengthening of the desired therapeutic action of digitalis if an excessive systolic effect opposes the necessary diastolic or if, owing to narrowing of the coronary artery, the action of digitalis has itself an inhibitive effect The combination is contraindicated when a quick systolic effect of digitalis is needed, since here quinin serves as an inhibiting antagonist and opposes the desired effect If as the result of auricular fibrillation, disturbances in ventricular activity and in the circulation arise, then the combination with digitalis is justified to strengthen the effect of the quinin Digitalis alone is contraindicated Cases of cardiac insufficiency with auricular fibrillation should be treated first with digitalis alone, then after compensation is established, with quinin alone, and if the conditions mentioned above are present the combination of quinin and digitalis may be used

*Oxyuriasis O Heubner—p 1
*Fatigue and Irritability P Karger—p 22
Endothelium Permeability P Hoffmann—p 39
*Incipient Scurvy E Nassau and M J Singer—p 44
*The Kidneys in Infants E Stransky and R Kochmann—p 63
*Blood During Loss of Weight A Balint and A Peiper—p 74
*Porridge in Infant Feeding B Epstein—p 85

Oxyuriasis—Heubner had a minute dendritic ulcer form in the cornea which was about a year in healing and one ophthalmologist said that he had encountered similar cases in persons with oxyuriasis Heubner had long been infested with the oxyuris and had been making a special study of his case Hemeralopia has also been noted in oxyuriasis His research has demonstrated that the course of this helminthiasis is by six or seven week cycles probably by new generations The vermifuge treatment is rendered more effectual by taking onions or garlic for six or seven days beforehand, three or four times a day, 15 or 20 gm of fresh scraped raw onions or garlic Then santonin or male fern put an end at

once to all disturbances A month passed without further signs of the helminths There can be no question of eradication however, until two months have passed without signs of the helminths By wearing tight bathing trunks at night, the pinworms that crawl out of the anus get caught in the fibers of the trunks and can thus be studied Treatment should aim to attack the new generation as it develops

Hypokolasia—Karger has coined this term to apply to a group of nervous affections characterized by early fatigue or other functional weakness of the inhibiting mechanism The result may be an abnormal exaggeration or an abnormal weakness of inhibitions This offers a new point of view for treatment of neuropathies For example in treatment of enuresis the child can be got up an hour earlier, so that, from lack of anything better to do he fills up the time before school by eating Or repose is enforced after dinner till the clock strikes so the child will linger at the meal instead of rushing through it to run out to play The aim in treatment is to conquer the inhibitions not to coddle them If a child cannot go to sleep unless the room is dark and quiet, combat this, instead of keeping the house quiet

The Endothelial Symptom in Infants—Hoffmann refers to the minute hemorrhages in the skin that develop after an elastic band has been applied to the upper arm drawn tight enough to congest the veins but not to shut off the radial pulse entirely This was supposed to be peculiar to scarlet fever, but has been found positive in various other infections Hoffmann's tests on the ten infants suggest that a lack of vitamins may also entail this abnormal permeability of the endothelium of the capillaries A positive response may thus warn of the necessity for adding accessory factors to the food

Impending Scurvy—Nassau and Singer describe a set of symptoms which warn that scurvy is impending In 50 per cent of thirty children who later developed scurvy, minute punctate hemorrhages in the skin had been observed, mostly in the face In 37 per cent, from two weeks to three months before the scurvy, blood had been noticed in the urine although the children seemed to be thriving Loss of appetite was noted in 50 per cent on an average of 17 months before the scurvy developed Inability to resist infection is another feature of this prodromal stage, as also the stationary weight

Renal Function in Infants—In this fourth report of research in this line, Stransky and Kochmann state that some infants eliminate water by means other than the kidneys in larger amounts than through the kidneys Epinephrin did not seem to modify kidney functioning but pituitary extract in large doses checked elimination of water by the kidneys it was thrown off by other routes Small doses of pituitary extract increased the elimination of sodium chlorid in the urine The details are given from nine infants and young children

The Blood During Sudden Losses of Weight—The experiments reported demonstrate that the blood may be abnormally concentrated or abnormally diluted in infants who are losing weight

Porridge in Infant Feeding—The advantages of giving a food less fluid than milk to infants with habitual vomiting are now thoroughly established The stomach contracts around the more solid food and this prevents swallowing of air and the expulsive contractions The infants thrived on the one to three teaspoonfuls of porridge daily (*weizengrutzebrei*), kept up for months In this article Epstein describes experiences with it for infants requiring a little supplementary food or to combat constipation in which it proved of great advantage

Ammonium Chlorid in Infantile Tetany—Freudenberg and Gyorgy report that by the internal administration of ammonium chlorid (from 3 to 7 gm per diem) to spasmophilic infants they were able to check the mechanical and faradic nervous hyperexcitability and rid the patients of the manifest symptoms of tetany The procedure is adapted to practical application but should be employed only in manifest and not in latent tetany In one case of postoperative tetany it was shown to be efficacious In some instances the medication had to be kept up for ten days It averts the acute danger and time is gained in which to bring about a permanent change in the condition by means of cod liver oil and quartz lamp irradiation Ammonium chlorid is preferable to calcium chlorid for the reason that it is pleasanter to take The writers have sometimes found it absolutely impossible to get children to take the required dose of calcium chlorid (from 6 to 8 gm) The effect of ammonium chlorid is, to be sure, only symptomatic

Agglutination in Diagnosis J and J Vorschutz—p 662
Water Test in Diagnosis of Gastric Ulcer F L Bonn—p 678

Freezing Point of the Blood—Elfeldt presents further evidence that the freezing point of the blood depends on a number of factors both renal and extrarenal His long tabulated series of cases of sound and diseased kidneys, enlarged prostate etc confirm the necessity for the subjects being in water balance for tests of the freezing point to be instructive

Distribution of Leukocytes—Ruef gives the leukocyte count in blood taken from different parts of the body before and after a major operation The findings throw doubt on the accuracy of estimation of the total leukocytes from the number found in the peripheral blood A man with 5,000 leukocytes in blood from the ear may have around 20,000 in blood taken from an internal organ

Influence of Testicles on Electric Excitability—In fourteen cases more or less of the testicles had been removed for various reasons and in twelve of these fourteen subjects the response to electric tests thereafter was much increased The results of experiments on dogs coincided with this The changes in electric excitability seem to be a manifestation of endocrine disturbance Investigation of the electric excitability may thus throw light on disturbances in the balance of the endocrine system

Spondylitis—Quincke has encountered a number of cases in which supposed muscular rheumatism of the back had persisted for several months but the tenderness of the spinous processes finally imposed the diagnosis of spondylitis In all there had been an acute infectious disease or suppurative lesion not long before The bacteria invade the bone marrow of the vertebrae early in acute infectious diseases, typhoid, a streptococcus process in a tooth or other infectious process This invasion may be the explanation of the pains in the back at the onset of typhoid and other infections The marrow

process usually retrogresses without leaving a trace, but occasionally it leads to actual spondylitis, and a trauma may first call attention to it He describes a number of cases, and emphasizes the necessity for greater care of the spine in acute infectious diseases, relieving it of weight bearing and warding off strain and trauma In one of the cases cited the spondylitis developed, with fever, two months after defervescence in typhoid

Agglutination in the Blood in Diagnosis—Vorschutz states that hemagglutination is identical with bacteria agglutination, also that it is an electric process and depends on the proportion of globulins The speed of sedimentation of the erythrocytes also depends on the proportion of globulin

The Water Test in Diagnosis—Bonn refers to the differentiation of gastric ulcer from cancer by the difference in the excretion of water and salt His tests failed to confirm recent statements to this effect

Heart Disease and Pregnancy—Nelius data confirm that it is almost impossible to foretell the outcome when a woman with heart disease becomes pregnant The course may be favorable with a serious valvular defect, and may be grave with an insignificant heart lesion Women with grave disturbances at one pregnancy may have no trouble at the next one and so on In his fifty-three cases in twelve years it was evident, however, that the earlier in the pregnancy compensation failed, the graver the prognosis With failing compensation, expectant treatment under close supervision may tide through to safety

The Kielland Forceps—Mayer concludes his illustrated description of this instrument and its application with the remark that it is not yet to be recommended to the general practitioner It has proved, he says, very valuable for certain conditions an actual *Zergeisterung* of the forceps procedure It was described in THE JOURNAL, July 9, 1921, p 142

Pubiotomy Outside of Pregnancy—Schmidt has constructed a pelvis dilator which screws the edges of the bone apart when the pubis is divided With this the limits for pubiotomy can be reduced to a conjugate diameter of 6 5 or even 6 cm This operation outside of pregnancy or very early in a pregnancy represents a much less serious operation than when done at term and the dilator insures that the cleft will not close up again

The Appendix and Affections of the Adnexa Uteri—Thaler reports that in 777 laparotomies performed during the past eleven years for inflammation of the adnexa in the Women's Hospital in Vienna he found thirty-one cases in which the appendix was adherent to the right adnexa A study of these thirty-one cases revealed that there was only one instance in which the appendix was diseased and the adherent right tube was healthy In the remaining thirty cases it could be shown from the anamnesis, the local findings and the behavior of the opposite adnexa that it was highly probable that at the time the adhesions formed the right adnexa were in an abnormal condition There was no evidence of a direct extension of an inflammation of the appendix to the central portions of tubes still healthy at the time of the formation of the adhesions

Delivery Thirty-Six Hours After Death—The macerated fetus measured 24 cm, and conditions showed that it had been expelled by gases within the uterus The woman of 32 had died two days after a chill and other symptoms had suggested possible criminal abortion

*Acute Nephritis without Albuminuria L Mayer—p 460

The Total Amount of Blood—Plesch advises against forbidding meat and salt for longer than six weeks, for any cause, but a protein-poor and salt poor day once a week is extraordinarily effectual in the chronic diseases of middle age Nearly all religions make fasting at some time a regular law but this provision undoubtedly at first was merely for hygiene His research has provided a base for venesection, fasting, and various forms of dietetic treatment, as he explains His tables show the blood findings in fifty cases, and the effect of venesection, etc

Test Hemoclastic Crisis—Holzer and Schilling noted a positive hemoclastic crisis with liver disease, and with congestion in the liver from heart disease also often after arsphenamin injections, and with subacidity, but the response was variable in infectious diseases The findings with various tests in fifty-one patients are tabulated Peptone had a similar action the number of leukocytes running up in the healthy, and dropping when there was liver disease

The Hemoclastic Crisis—Worms and Schreiber report thirty tests on twenty-five patients They regard the leuko-Widal, as they call the test, as indicating merely a change in the distribution of the leukocytes The response is not very constant or reliable, and can be depended on as an important clinical symptom only when the reaction is intense or there are special circumstances The reaction is not proportional to the severity of the liver process or its nature, and a negative response does not exclude liver disease

Surface Tension of the Urine in Prognosis—Schemensky was surprised at the close parallelism between the stalagmometer curve and the clinical course in his latest series of nine cases of acute articular rheumatism, glomerular nephritis and tuberculosis of the lungs In one other case of nephritis the stalagmometer quotient has kept high although the disease has long been progressively improving, no explanation of this behavior can be discovered It is possible that the apparent cure of the nephritis in this instance may be deceptive

The Blood Picture with Scurvy—Hausmann classifies the leukocytes by the Arneth differential count in scurvy, specifying some characteristic changes, reduction in numbers of neutrophils and absence of features suggesting infection

Amylase in Diagnosis—Block regards the amylase (diastase) in blood and urine as an aid in the diagnosis of the most diverse pathologic conditions as he describes, with nearly four pages of bibliographic titles set solid

Size of Erythrocytes—Csáki has often noticed that the size of the erythrocytes seemed to correspond always to the hemoglobin percentage. Any change in one was accompanied so promptly by a corresponding change in the other that he is inclined to believe that the red corpuscles can regulate their own *hemoglobin content*. *With nephrosis*, there is microcytosis probably from the increase of salt in the plasma. *With nephritis*, on the other hand, the size of the erythrocytes is not modified.

Prognosis of Kidney Disease—Litzner's thirteen pages of tabulated details of 75 cases of nephritis allow retrospective analysis of the probable outcome. The more intense the hyposthenuria, the nearer the end. Some with arteriosclerotic contracted kidney survived for many years, up to decades. The prognosis at the time in the 75 cases was correct in all but 5, in one of these it was too favorable, in the others too unfavorable. His tables list fourteen kinds of details.

Acute Nephritis Without Albuminuria—Two cases are described. In one the tuberculous young man was in good condition when he suddenly developed acute glomerular *nephritis with anuria and dropsy*, but no albumin for a week. Then came slight albuminuria, and death the eighteenth day. The acute nephritis without albuminuria was mild and transient in the other young man.

*Ability of the Young to Produce Precipitins. F Luska—p 249

Ability of Young Individuals to Form Specific Precipitins—A perfect parallelism could be demonstrated in young rabbits between the H ion concentration of the serum, the flocculation of the serum by small amounts of alcohol, and the formation of specific precipitins. In very young rabbits with a p_H smaller than 7 the flocculation required more alcohol and no specific precipitin formation could be obtained by injections of horse serum. The increase in p_H was *not* due to the injections as it occurred in the untreated controls too but not in the mother of the rabbits serving as positive control. The increase of the ability to flocculate with age points to Ruzicka's theory of the hysteresis of the protoplasma. The impossibility to find specific precipitins in rabbits 4 to 5 weeks old means only that it is not possible to demonstrate their presence by the methods now used.

Tuberculosis in Rural Districts. S Savonen—p *186*

Xanthosarcomas in Tendon Sheaths—In connection with 4 cases personally observed and one of multiple xanthoma Krogius reviews the history of these growths, and protests against the general assumption that they are comparatively benign tumors. Of the 93 cases compiled by Tourneaux in 1913 the finger was the site of the lesion in 48, the hand in 12 and the forearm in 6. 19 were on the foot and one on the leg. The age ranged from 6 to 80. These tumors may grow very slowly and be stationary for years, and then start to sudden rapid growth or they may be malignant from the first. Those on the fingers have seemed to be the most benign while those on the forearm, hand and foot seemed most *malignant. In one of his cases there was local recurrence a* year after removal of the tumor in the foot. In 6 of the total 93 cases there was metastasis in lungs, liver, etc. and recurrence was known in 21. He reiterates that the general assumption that tendon sheath tumors are benign growths must be abandoned except for the small ones on fingers. All others demand prompt removal and if adjacent tissues are involved testifying to extreme malignancy, amputation should be considered as for malignant disease in general.

Chronic Stomach Disturbance—Ehrstrom remarks that notwithstanding the roentgen rays, the stomach tube and the findings at operations there are certain cases of stomach disturbances in which no explanation can be found for the patient's complaints. On the other hand, grave organic lesions may develop without subjective symptoms. Krogius' compilation of 129 cases of perforation of a gastric ulcer included 15 in which the perforation was absolutely the first symptom to call attention to the stomach, and 8 in which there had been subjective symptoms for only from one to four weeks although in some the ulcer was hard and evidently of long standing. With symptoms typical of ulcer, the operation may show the stomach apparently intact, gastro enterostomy however cures the symptoms. The disturbance seems to be a chronic intermittent dyspepsia. (A similar article was briefly mentioned on page 88.)

The Arteries in the Kidneys in Relation to the Blood Pressure—In the 128 cadavers in which Wallgren paid special attention to the renal arteries nothing was found which conflicted with the assumption that the severe changes in the kidney vessels were due in large part to the high blood pressure that had prevailed during life. There was nothing to prove that the arteriosclerosis had preceded the hypertonia.

Lack of Water in the Tissues in Relation to Acetone Elimination—Ehrstrom noticed in a case in 1906 that after a period of profuse vomiting there was a strong odor of acetone on the breath. It subsided after saline infusion. Other experiences of the kind since have confirmed the connection between the condition of water deficit entailed by profuse diarrhea, repeated vomiting, etc. and the appearance of acetone in the breath and urine. In fever cases with much acetone his investigations always revealed that there had been unusually small intake of fluids. Increasing the

intake of fluids seemed to reduce the acetone. This sequence explains also the acetonuria in the insane refusing food, as they refuse food, the intake of fluids is proportionately reduced. The thirst and the polyuria in diabetes throw further light on this connection. Both the water deficit and the acetone excretion are linked with the excess of sugar in the blood, the tissues suffering from the lack of fluids and of carbohydrates. Ehrstrom's article has already been mentioned, p. 88.

*Influence of Exercise on the Temperature. C. H. Wurtzen and C. Holten.—p. 133. Begun No. 7, p. 101.

Influence of Exercise on the Temperature in the Tuberculous.—Wurtzen and Holten give 19 pages of the tabulated findings in regard to the stage of the tuberculosis and the fluctuation of the temperature after a 15 minute walk and after a 10 minute and a 5 minute walk as also in 27 healthy controls. The temperature showed some modification up or down in 52 per cent. of the tests on the normal after the 5 minute walk, in 64 per cent. after the 10 minute, and in 39 per cent. after the 15 minute walk. In the tuberculous the rise in temperature might occur a little earlier and last longer than in the normal, but the percentage affected was only from 15 to 27 after the 5 minute walk, from 27 to 45 after the 10 minute, and from 59 to 61 per cent. after the 15 minute walk. There is thus no regularity in the behavior of the temperature after exercise in either sick or well; no definite limit between the normal and the pathologic.

April 20, 1922, 84, No. 16

Ulcerative Gastritis. A. Borgbjerg.—p. 375.

Radiotherapy of Exophthalmic Goiter.—Fischer reviews his 490 cases. The improvement realized by the radiotherapy has persisted in the majority during the years since. His entire 490 cases included only eleven men. In 8 cases the thyroid had been previously resected. The interval from the first symptoms ranged from six months to five years in the majority and the age in all from 24 to 63. Fourteen cases are described with illustrations. The weight increases as the benefit is felt, a gain of 5 kg. is common and gains up to 10 or 20 kg. have been observed. Sweating and diarrhea were promptly arrested as also the glycosuria noted in 3 per cent. Tachycardia was the most constant symptom and this disappeared entirely in 25 per cent. and was materially modified in a further 50 per cent. In the others, the pulse kept at about 100 to 120 but the patients felt well. Exophthalmos was the hardest to influence of all the symptoms whether treatment was by raying or by operation, but it subsided completely in some. The effect was more pronounced the more recent the exophthalmos. In about a third of the patients, the goiter persisted, although the general condition had been very much improved. In the other two thirds the thyroid returned more or less completely to its normal size.

The soft goiters yielded soonest, the hard first became soft, and then slowly subsided. Recurrence was very rare in private patients, but certain working women had the symptoms return later, and a second course of treatment was given. Four cases are on record in Danish literature in which the patients died after roentgen exposures, and the radiotherapy was incriminated for the fatalities. But Fischer here reports two similar cases of suddenly fatal exophthalmic goiter differing only in that radiotherapy had not been applied. Otherwise the conditions seemed to be identical. All these fatal cases were in the severer forms of exophthalmic goiter and these forms call for extra caution. In the 30 cases of pregnancy while the women were under observation no influence on the gestation from the radiotherapy could be discovered, and the pregnancy did not aggravate the hyperthyroidism. In the severe cases the cross-fire dose was 3 H units, if this was borne well then 8 or 10 units a month later. The mild cases were given the latter dose to start with. In mild rudimentary cases the radiotherapy usually insured a permanent cure. If the roentgen treatment had not benefited in two or three months, it was considered useless to continue it. He says that the radiotherapy never renders an operation later more difficult. Stationary chronic forms should be given operative treatment on account of the danger of degeneration of the myocardium, radiotherapy is only the second choice in this group. The more recent the case, the greater the chance of cure under radiotherapy, which may be said to be quite harmless.

April 27, 1922, 84, No. 17

*Cholelithiasis. S. Hansen.—p. 405.

Gallstones.—Hansen declares that it is not a casual happening that there were only twenty-six deaths from appendicitis during a recent twenty-one months while there were forty deaths from cholelithiasis although the total of cases, 293, was much less than of the appendicitis cases. Appendicitis is treated rationally, the surgeon is called in early while delay in the differential diagnosis and expectant treatment wastes valuable time with gallstones. In nine of the forty cholelithiasis deaths the patients were in the medical ward. The bile ducts were normal in 43 per cent. of the 293 cases, cancer was found in the gallbladder in three cases.

May 11, 1922, 84, No. 19

Shape of Chest. *Determines Shape and Position of Stomach. K. Fabricius.—p. 479.

The Diet in Tuberculosis.—Hindhede has long been the apostle of the advantages of a milk-vegetable diet. His dictum is *Stinkende ekskrementer* are incompatible with well-being. In this communication he emphasizes that no exception should be made for the tuberculous. Otherwise we handicap and cripple them in their fight with the disease. At Leysin Rollier has sanatoriums for all purses and those paying the highest prices are given meat, while in the cheaper establishments the fare, he says "out-Hindhedes Hindhede." But the statistics show, year after year, that the cures are more numerous and more complete in the less expensive than in the high priced quarters. Rollier told Hindhede that he is convinced that it would be to the great advantage of the tuberculous to drop meat from the menu. But he feared that if he did this his motives would be misconstrued. Hindhede presents further an array of data from various sanatoriums in Switzerland and Denmark which justify the conclusion, he says, that there is no evidence that a diet rich in meat and fat offers any advantage for the tuberculous.

Test for Chlorids in the Blood.—The Hagedorn and Norman-Jensen micromethod is applied as for sugar in the blood and the filtrate is tested for chlorin by the Vollhard method. This micromethod is not so simple as Bang's, but comparative tests showed that it is considerably more exact. The technic is described in detail.

The Bang Test for Chlorids in the Blood.—Iversen reports experiences which confirm that the Bang micromethod gives from 1 to 3 per cent. too low values for the chlorin content of the blood.

VOL 79, NO 3 CHICAGO, ILLINOIS JULY 15, 1922

BRONCHIAL LYMPHADENOPATHY, NONTUBERCULOUS*

E C FLEISCHNER M D

SAN FRANCISCO

The tremendous number of observations that have been made on tuberculosis of the bronchial lymph nodes during the last hundred and fifty years yields a literature fairly surcharged with experimental and clinical data An investigation of the work that has been done on the acute or subacute bacterial infections, on the other hand, is particularly striking on account of its paucity

Several explanations can be deduced for this interesting status It has been recognized, ever since the publication of Lalouette in 1780 (Traite des scrofules), and Leblond in 1824, that tuberculosis of the bronchial lymph nodes is a distinct disease Furthermore, Louis (1825), Laennec (1837), Fischer and others have emphasized the fact that tuberculosis is the most common disease of these lymph nodes and it occurs more frequently in them than in any other viscus of the body It must be remembered that this information has been largely gathered from postmortem examinations, so it is not surprising that so much attention has been focussed on it Acute and subacute infections of the bronchial lymph nodes have been studied by very few men, for the following fundamental reasons (*a*) necropsy material has always been very scarce, (*b*) when available, it has been so overshadowed by the associated lesions in the respiratory organs, that its importance has been overlooked, and (*c*) the diagnosis may for obvious reasons be considered most difficult, both as to classic symptomatology and physical signs

THE LITERATURE

It is highly interesting, in referring to certain fundamental facts that have been deduced concerning the anatomy and physiology of the bronchial lymph nodes, to review briefly some of the pioneer work that has been accomplished Modern medicine is too much inclined to take for granted the investigations of the eighteenth and nineteenth centuries, forgetting men whose efforts and studies should always be a source of great stimulation Becker, in 1826, following the researches of Mascagni and Cruikshank, divided the thoracic lymph nodes into (*a*) parietal and (*b*) visceral It remained for a Frenchman, Barety, however, so comprehensively and thoroughly to describe these glands, that, up to the present time, practically nothing has been added to his observations His description has become so classic that scarcely a reference can be found, either anatomic or clinical, that does not quote him in great detail He describes a tracheobronchial region that is comprised of all of the mediastinum except the heart It is bounded above by the superior opening of the thorax, below by a plane where the pulmonary veins empty into the left auricle It is limited in front by the sternum, behind by the vertebral column and laterally by the lungs Barety divides the mediastinal glands into three groups (1) pretracheobronchial right and left, (2) intertracheobronchial or subbronchial, right and left, and (3) interbronchial

1 The pretracheobronchial group of glands occupies the anteriosuperior side of the obtuse angle, which is formed externally by the trachea and principal bronchus They are situated on both sides, but hypertrophy and degeneration are found more commonly on the right

2 The intertracheobronchial or the subbronchial right and left groups of glands lie on the under surface of the main bronchus They are more numerous on the right than on the left side

3 The interbronchial groups of glands occupy the angle of division of the bronchial tubes They are found in the bronchial divisions up to the fourth order

The physiology of the lymph nodes is so intimately associated with pathology and bacteriology that their normal function has been extensively studied by investigators in these allied sciences Councilman, in the Harvey lectures, 1906-1907, in describing the changes in the lymphoid tissue in certain of the infectious diseases, stresses several salient facts In the masses of small lymphoid cells, particularly along the convexity are round or oblong foci of differentiated cells They were first described by His, and later more fully studied by Fleming, who regarded them as centers of cell production or germinal centers He especially emphasizes the fact that, in the study of the lymphoid tissues, one is impressed by a striking feature, i e, its preponderance in childhood They play an interesting role in the pathology of the tissue Oertel first demonstrated that, in diphtheria, areas of necrosis occur in the lymph nodes, corresponding to the germinal centers Similar changes are observed in scarlet fever, variola and other conditions

Manfredi, in an experimental study on the function of lymph nodes, found that they act against bacteria by (1) filtration, (2) diminishing the strength of the bacteria, whereby their virulence is partly or wholly lost, and (3) bringing into contact with the invading organisms the immune substances that are elaborated by the body in general Next to the skin and mucous membranes the lymph nodes act as the strongest barrier against bacteria Manfredi's experiments throw inter-

* From the Department of Pediatrics University of California Medical School

* Chairman s address read before the Section on Diseases of Children at the Seventy Third Annual Session of the American Medical Association, St Louis May, 1922

esting light on the question of latency of bacteria in the lymph nodes, a subject to which too little attention has been paid in the study of infection and immunity He found that *Staphylococcus pyogenes-aureus* lived latently in the lymph nodes of guinea-pigs forty days and in those of dogs, thirty days, while *B typhosus* was present in guinea-pigs sixty days and in dogs thirty days Pneumococci that were recovered from the lymph nodes did not kill rabbits, the same organisms cultivated from the blood or spleen were fatal to rabbits Typhoid bacilli recovered from the glands lost their virulence for guinea-pigs, while the virulence of staphylococci and tubercle bacilli was definitely diminished by passage through the lymph nodes

Baumgarten found that, following the intravenous injection of tubercle bacilli, animals developed a generalized tuberculosis of the lymph nodes, and that only when the glands could no longer hold back the bacteria did they get into the blood stream through the veins and invade the other viscera He considered this highly presumptive evidence of the elective capacity of the lymph nodes to absorb circulating bacteria

Loomis, Kalbe, Piccini and many others were able to demonstrate by animal inoculation the latency of tubercle bacilli in the bronchial lymph nodes of people in whom there was neither macroscopic nor microscopic evidence of tuberculosis Kalbe, by cultivating and injecting lymph node material into animals, recovered streptococci, staphylococci, pneumobacilli and pneumococci, the last two of which were fatal in white mice in twenty-four hours, while the first two produced local abscesses in a number of instances Perez, in eighty-eight cases, found latent bacteria most frequently in the subcutaneous lymph nodes, then in the bronchial group, and least often in the mesenteric glands

The incidence of enlargement of the lymph nodes in childhood is so striking as scarcely to warrant statistical verification It may, however, be well to comment on the fact that Laser, in examining 2,506 children, found that those from 7 to 9 years of age had enlargement of the glands in 96 per cent of the observations, from 10 to 12 years, in 91 6 per cent, and from 13 to 14 years, in 84 per cent Baer, reporting on twenty-five new-born infants and 350 older infants and children, rather cynically stated that nearly all children had enlarged lymph nodes

In summarizing these investigations in an effort to determine their bearing on infections of the bronchial lymph nodes, the following facts assert themselves

1 Lymphoid tissue is strikingly predominant in childhood
2 The activity of the tissue can be judged by the presence of the germinal centers, which are rarely absent during this period
3 Enlargement of the lymph nodes in the child is so common as to be almost constantly demonstrable
4 Bacteria, in a latent stage, are present in many of these glands
5 The virulence of these organisms is frequently attenuated

It must, therefore, be strikingly apparent to all clinical observers that the lymphatic apparatus in childhood is constantly engaged in a system of defense against pathogenic organisms, whereby there is gradually developed for the body an immunity against these bacteria Only a slight realization of this stupendous function is necessary to make one appreciate the great incidence of infections of the bronchial lymph nodes

A careful survey of the literature bearing on the clinical signs of acute and subacute bronchial lymph node infections reveals the striking fact that it is extremely difficult to find records of observations sufficiently detailed to make a symptomatic diagnosis possible Zabel quotes no less an authority than Heubner, who states in his textbook that the disease picture in enlarged bronchial glands is uncertain, and no one symptom can be a guide to an absolute diagnosis

In an effort more definitely to stabilize the clinical manifestations of this important subject, a study has been made of a large number of cases in which physical examination and roentgen-ray findings have, as far as is possible, established the presence of an acute or a subacute bronchial lymphadenitis

CASE GROUPS

The cases divide themselves into five groups, which may be arbitrarily described as

1 Those in which malnutrition is the cardinal symptom malnutrition type
2 Those in which frequent colds or persistent cough is the primary symptom subacute bronchitis type
3 Those in which a pertussis-like cough is the most striking evidence pertussoid type
4 Those in which a low grade febrile course is the essential complaint chronic febrile type
5 Those in which there has developed persistent attacks of asthmatic bronchitis following an acute respiratory infection usually a pneumonia asthmatic type

It may be presumptuous to attempt a classification of this sort in a disease picture that has always been accepted as somewhat ambiguous In an effort to justify this classification, a more detailed outline of the typical history and symptomatology in each group is desirable

1 *Malnutrition Type*.—These children are brought for medical advice usually on account of their general appearance The most common complaint is that they have not looked well for a variable period, from several weeks to as long as from two to three years They are often below weight and give a history of not having gained for a long time The appetite is poor and the color pale Fatigue and languor are frequently a source of worry, and the complaint is elicited either that the child never cares to play or exercise, or that, if persuaded to indulge in this form of recreation, he becomes fatigued in a short time Digestive symptoms may develop, and one not infrequently hears that, incidental to his general lack of well being, the child has equivocal gastro-intestinal disturbances, for which there is no explanation Notation may have been made of a slight afternoon rise in temperature, although this is rare

2 *Subacute Bronchitis Type*.—The clinical picture in this class of case is somewhat variable Most frequently there is present a chronic cough, with which there is little, if any, expectoration The cough is liable to be more pronounced at night, although it is rarely severe enough to wake the child In other cases, the essential element is the marked frequency of infectious colds, in which, notwithstanding their mildness, the symptoms persist for a long time These children are much more liable to have a distressing cough with the upper respiratory infections, and when all other signs of an inflammatory process have subsided, the cough remains an irritating feature Any of the general evidences of toxemia present in the malnutrition

type, loss of weight, pallor, poor appetite or lack of energy, may be present

3 *Pertussoid Type*—From an historical and from a clinical standpoint, this group of cases presents the most fascinating characteristics In 1780, Lalouette, commenting on the symptoms in tuberculosis of the bronchial lymph nodes, called attention to the persistent cough, which was so changed in character that a diagnosis of pertussis was frequently made Leblond, in 1826, described this same cough in patients with enlarged bronchial glands Ley (1834) noted, in children with enlarged glands, attacks of violent coughing with a sonorous inspiration resembling whooping cough Verliac, in 1865, stated that if the spasmodic cough lasted too long after pertussis, bronchial gland disease must be suspected Daga emphasized the fact that the cough in bronchial gland involvement often returned in crisis, and that it was frequently spasmodic and had a peculiar sound, like the bark of a dog Finally Rilliet and Barthez commented on the fact that in these cases the diagnosis between pertussis and bronchial adenopathy was often difficult, if not impossible

A careful consideration of the histories of this type of case reveals some interesting observations It seems definitely possible to divide this group into several subdivisions, depending on the manner of development of the classic symptoms One striking feature of these subdivisions is that they seem strongly influenced by the nature of the etiologic agent Incidental to the epidemics of influenza that have been present during the last few years, cases of this type have been common They group themselves into two subdivisions (*a*) cases in which the pertussis-like cough has developed within a few days of the onset of the disease, and (*b*) cases in which this peculiar symptom has not become manifest for a considerable period of time, during which the essential symptom has been an ordinary cough incidental to the acute bronchitis

The children in the first group are taken ill usually with the symptoms of a mild upper respiratory infection, malaise, moderate rise in temperature, coryza and slight cough Within from two days to a week, these symptoms disappear, and the patient develops a cough which is at first described as harsh and barking and which rapidly becomes paroxysmal, developing a whoop so like pertussis as to make the differential diagnosis very difficult There are, however, several important distinguishing features in this type of bronchial gland disease, which usually make its differentiation from whooping cough possible (1) The paroxysmal character of the cough develops within a much briefer period, a few days instead of two weeks (2) The actual length of the paroxysm preceding an inspiratory whoop is shorter than in whooping cough (3) Vomiting, while present, is less common (4) Children exposed may develop the same syndrome, but often only show the signs of a mild upper respiratory infection (5) The course of this group of cases in which the characteristic whoop is developed in a few days is usually much shorter than in pertussis, the paroxysmal cough disappearing at times in from one to two weeks

The cases in the second group are as a rule more severe from the onset, and the symptoms of an acute bronchitis are more striking than those of the upper respiratory tract After the symptoms of acute intoxication have disappeared, the cough persists, and its intensity is out of proportion to the physical signs ascribable to changes in either the lungs or bronchial tubes The cough, which is at first harsh and barking in character, may retain this peculiarity, or may become distinctly paroxysmal and finally develop a typical whoop, which may last for many weeks or, rarely, for several months Slight afternoon rise in temperature is occasionally present and, depending on the degree of toxemia, any of the symptoms described in the malnutrition type of the disease may be in evidence

It is, by inference, perfectly apparent that all types of bronchial lymph node disease may develop following any respiratory infection in the pleura, lungs or bronchi, irrespective of the etiology There are, however, two distinct diseases following which the chronic pertussoid type of bronchial lymph node disease is extraordinarily common, namely, measles and pertussis The frequent incidence of this situation has been responsible for erroneous deductions, particularly on the part of the earlier clinicians See, in 1854, submitted a work in which he proposed to show the analogy which existed between pertussis and certain of the eruptive fevers, especially measles He contended that the cough, the fever, the catarrh and the contagiousness were comparable He based his contention on his own observations and on an historical study which showed that, since 1732, many had been impressed either by the simultaneous appearance of the two diseases or by the observation that pertussis frequently followed measles

In view of the fact that nothing was known at the time these conclusions were drawn concerning either the physical or roentgen-ray diagnosis of bronchial lymph node disease, and since, following measles, it is most common to find secondary infections of the bronchial glands with symptoms suggesting pertussis, it is not surprising that errors should have been made Many of the earlier writers were likewise struck by the similarity of the clinical picture of tuberculosis of the bronchial lymph nodes and pertussis, and descriptions were also given of cases of chronic pertussis lasting sometimes as long as from two to three years, with a characteristic cough As early an observer as Lalouette realized, in 1780, that this peculiar character of the cough was probably due to vagus irritation, but it was not until much later, in the middle of the nineteenth century, that the bearing of secondary involvement of the bronchial lymph nodes in pertussis was appreciated Noël Gueneau de Mussy, taking up the question of the analogy between bronchial adenopathy and pertussis, says

> I have already noted the pertussoid character of the cough in certain types of adenopathy It is difficult not to admit that this is due to a direct or reflex action on the vagus by the diseased glands I do not contend that in pertussis an adenopathy is the intermediary necessary for vagus irritation I believe though that in many cases the glandular involvement mixes its symptoms with those of the disease of which it is the complication I am disposed to attribute to pneumogastric irritation, by enlarged bronchial glands, the so-called cases of chronic pertussis, which last sometimes from two to three years Without affirming that the convulsive cough of pertussis which seems to point to an excitation of the vagus, is associated with an adenopathy, and without denying that this neurosis of the tenth pair of nerves can be a direct manifestation of the malady, one can at least point to the fact that the laryngeal spasm in pertussis occurs only several days and even weeks after the beginning of the pertussis and after the development of the bronchial congestion If one

can show that, at this point, signs of an adenopathy appear, the correlation of the two phenomena would be infinitely probable

Gueneau de Mussy's contentions grow much more probable and logical when one remembers the pertussoid cases previously described, in which the characteristic cough develops only a few days after the onset of influenza infections, in which by roentgen-ray and physical examination enlargement of the bronchial glands is definitely demonstrable

4 *Chronic Febrile Type*.—These are the cases which are the greatest source of concern to the family and the medical advisor. They are characterized by a low grade febrile course, usually without any subjective symptoms beyond those associated with a slight toxemia, such as pallor and languor. The condition may start as a mild upper respiratory infection, more commonly an influenza than any other, so benign in character that the mother is instructed to keep the child in bed until the temperature has been normal for from twenty-four to forty-eight hours. Much to the surprise of every one, the temperature does not reach normal and there is an afternoon rise in temperature of from a half degree to 2 degrees, rarely higher, that may last weeks, months and even years. At times, there are present the characteristic symptoms seen in any chronic infection. At other times, the well-being of the child is not disturbed in the least, and, eventually, the rise in temperature is ignored in the absence of other signs of infection.

5 *Asthmatic Type*.—Considerable exception may be taken by clinicians, particularly those interested in protein hypersensitiveness, to the assumption that there is a type of asthmatic bronchitis due to subacute infections in the bronchial lymph nodes. This is particularly so when one realizes that most children who suffer frequent attacks of asthmatic bronchitis develop enlargement of the glands, incidental to the absorption from the low grade inflammatory process in the bronchial mucous membrane. On the other hand, every one recognizes that there is a definite form of hypersensitiveness which evidences itself by bronchial spasm, in which the sensitizing protein is bacterial in character, and what focus, in view of the experimental work that has been done on the latency of bacteria in lymph nodes, can play a more effective role than the bronchial glands? Add to this evidence the fact that, in these children, a history is frequently elicited of attacks of asthmatic bronchitis beginning following an acute upper respiratory infection, usually a pneumonia, and the circumstances combine to make the hypothesis even to the most skeptical, a tenable one.

PHYSICAL EXAMINATION

In estimating the value of physical signs in the diagnosis of bronchial lymph node disease, it seems advisable to divide the upper portion of the thorax into four divisions, in order of their importance: (1) the spinal column between the seventh cervical and the fifth dorsal vertebrae, (2) the interscapular regions, (3) the superior sternal regions, including the sternoclavicular articulations, and (4) the regions to the right and left of the sternum between the clavicle, above, and the third rib, below.

1. It is to d'Espine of Geneva that the greatest recognition is due for his contribution of the most consistent physical sign in bronchial lymph node disease. This sign, which now so familiarly bears d'Espine's name, was first reported to the French Academy of Medicine in 1904, although the original observation had been made in 1889, while he was studying the early diagnosis of pneumonia of the upper lobe. One can do no better than to translate literally a short description of the sign as originally reported:

> The first signs of bronchial adenopathy are furnished exclusively by auscultation of the voice and by observing its character, nearly always in the region of the vertebral column, between the seventh cervical and the first (upper) dorsal vertebrae, either in the fossae under the spinous processes or lower down in the interscapular spaces. The sign consists in a timbre (quality) added to the voice, which one can call chuchotement (whispering in the ear or whispered pectoriloquy) in the first stage and bronchophony in a more advanced stage.

D'Espine comments further on his observations:

> In young infants, it is necessary to auscultate the quality of the crying voice. In a normal child, the characteristic bronchial breathing emanating from the trachea ends abruptly at the seventh cervical vertebra, where the lungs begin. In bronchial adenopathy this bronchial breathing extends to a varying degree into the space between the seventh cervical and the fourth or fifth dorsal vertebra, corresponding to the last part of the trachea and the bifurcation of the bronchi. Sometimes in extensive adenopathy, the bronchophony extends to the region of the lamina, more to the right than to the left. If auscultation of the spoken voice or the cry does not give a satisfactory result, one can try the whispered voice in children who cooperate and get an aphonic pectoriloquy (chuchotement). It has the same value as bronchophony. This bronchophony is the earliest and sometimes the only sign of bronchial adenopathy. In certain cases, however, one can also find, on percussion over the last cervical and upper dorsal vertebrae, definite dulness. Increased dulness in this region always coincides with intense bronchophony.

In a later contribution, d'Espine further emphasizes the value particularly of the whispered voice in eliciting his sign and says:

> The sign is most obvious if one makes the child speak or count in a low whisper. The voice is then accompanied by an added whispering sound localized to one or two vertebrae or possibly extending to the fourth or fifth. Bronchial breathing over this area has the same diagnostic value except that it is an indication of more extensive enlargement.

It may be advisable, in briefly commenting on d'Espine's original article, to call attention to the fact that some confusion has occasionally occurred on account of errors in translation. If care is not taken in translating "les premieres vertebres" referring to the upper dorsal, in the plural, the whole sense of the observation is lost. As a matter of fact, it is fairly generally recognized that, in older children, it is within normal limits to have what appears to be a positive sign over the seventh cervical or first dorsal vertebra without enlargement of the bronchial glands. Koranyi stressed this point and contends that pectoriloquy is only indicative of large lymph nodes if it occurs below the seventh cervical vertebra in young children, below the first dorsal in those 8 years of age, the second dorsal in those of 12, and the third dorsal in children 15 years old. The sign is brought out much more clearly if the child is instructed to bend the head slightly forward and fold the arms in front of the chest.

2. The spaces between the spine and the scapulae, even though their importance has been discredited by the French school, offer interesting and frequently striking evidences of bronchial gland disease. Dulness in this area, with characteristic auscultatory changes, is of greatest diagnostic value. The breath sounds,

particularly expiration, are prolonged and harsher than normal, and at times bronchovesicular or even bronchial breathing may occur In simple bronchial lymph node disease, without an accompanying bronchitis, adventitious sounds are conspicuously absent

3 Barety, whose epoch-making thesis on disease of the bronchial lymph nodes has already been discussed, lays special emphasis on the importance of the superior sternal regions in physical examination He briefly quotes Fonssagrives, who, in 1861, first described the percussion of the superior sternal region in tuberculosis of the bronchial lymph nodes, and noted the presence of dulness at the sternoclavicular articulation, although he did not appreciate its importance Whereas dulness in the superior sternal region is a characteristic sign in enlargement of the bronchial lymph nodes, it can be definitely stated that in the series of nontuberculous cases on which this communication is based, its incidence was definitely less frequent than either d'Espine's sign or interscapular dulness

4 Changes in the regions to the right and left of the sternum between the clavicle and the third rib are not encountered as often as those previously described, but when present they are, to say the least, most striking Dulness often begins at a definite point to the right and left of the sternum, and increases as the midline is approached The limit of this dulness to the right or left can often be definitely marked by dropping a line from the clavicle, either at its midpoint or at the junction of the middle and inner thirds, to the third rib

Auscultation over this area shows usually prolonged and harsh respiration, occasionally in both stages, but more frequently confined to the expiratory murmur The degree of this may be so great as to make the breathing bronchovesicular or even bronchial In some cases, on the other hand, the most striking sign is diminished breathing At times, this diminished breathing may be bronchovesicular in character Rales, in this region as in the interscapular space, are usually absent, except in the presence of bronchitis

ROENTGEN-RAY DIAGNOSIS

It is not within the scope of this paper to enter into a full discussion of the problem of the roentgen-ray diagnosis, but accuracy in estimating the extent of bronchial lymph node involvement is so essential that certain details of the value of the roentgen ray must be considered In establishing a positive diagnosis of bronchial lymphadenopathy, it is certain that the roentgen-ray examination is of less importance than either the history or the physical examination, but as an adjuvant its value cannot be overestimated Furthermore, stress must be laid on the fact that there will always be cases of unexplainable malnutrition in which there is an absence of physical signs, and in which roentgen-ray examination and that alone will establish a positive diagnosis

TUBERCULIN REACTION

It is perfectly obvious, without further comment, that the great problem in the management of this interesting disease is the exclusion of tuberculosis Without entering into an argument as to the relative value of the Pirquet and intradermal reactions, it will suffice to quote no less an authority than d'Espine, who says, "Von Pirquet's sign, which I use daily, will settle the question" There can be no question that, in a vast majority of cases, this conclusion is correct If doubt persists in spite of a negative Pirquet reaction, the problem can be further elucidated by the application of the intradermal test

TREATMENT

The treatment of nontuberculous bronchial lymphadenopathy may be discussed under three main headings rest, fresh air and diet The details must vary with the individual case The importance of avoiding fresh infection, particularly exposure to tuberculosis, cannot be overestimated In a general way, it may be positively stated that there is no disease, the management of which is so difficult, on account of its tediousness, for both the mother and the physician On the other hand, it is difficult to imagine any condition in which the results are as brilliant, if the family is made to realize that a disease is being combated in which the results are essentially slow, even though the outcome is practically always favorable The role of drugs in the general management of these cases is, to say the least, a secondary one Nothing further need be said on this phase of the subject, beyond calling attention to the fact that iron, iodin, cod liver oil and a few other less important preparations have been recommended In cases with secondary anemia, they may be of some value, but even here it is doubtful whether better results cannot be accomplished by simple hygiene and dietetic measures As in the treatment of lymph node disease in the cervical region, too much emphasis cannot be laid on the importance of removing foci wherever they exist It may be well briefly to outline certain variations in the treatment, depending on the character of the individual case In the malnutrition type of the disease, children must be kept in bed in the fresh air, preferably out of the city, until they are running a normal temperature, and until the behavior of their weight curve is such that one can be sure that the infection is under control The treatment is a matter often of several months' duration When it seems advisable to permit more liberty, the gradual assumption of the following regimen will be found most advantageous (1) breakfast in bed, (2) arise at 10 o'clock, (3) rest one hour after mid-day dinner, (4) retire at 5 o'clock, (5) supper in bed, (6) at least twelve hours' sleep at night How long these children must be kept out of school it is difficult to say It is better that the child be absent from school too long than too short a time In severe cases, the patient must be excluded from school at least a year The reasons are obvious enough when one realizes how susceptible these children are to fresh infection The diet in these cases must be a general one, except that it has been found beneficial to insist on the daily consumption of a quart of milk in all cases in which there is no idiosyncrasy

The management of the pertussoid type of cases requires certain special methods of treatment The degree of rest in bed depends on the temperature curve Any of the drugs used in pertussis, belladonna, antipyrin or bromid, may prove of value, and, above all, the use of opium, particularly to prevent the irritating cough at night, which disturbs the sleep, is to be recommended If the child vomits after eating, the mother must be instructed to feed him immediately, because no one element in these cases is so conducive to a chronic course as loss in weight The methods of treatment outlined for the malnutrition and pertussoid type of case may be combined in handling these children in whom bronchial gland involvement is responsible for repeated or lasting upper respiratory infections, par-

ticularly bronchitis The management of those cases running a chronic febrile course depends essentially on the stage of the disease at which the patients are first placed under medical observation If they have been treated for an acute upper respiratory infection, particularly an influenza, and it is found after several days that a low degree afternoon temperature is persisting, they should be kept in bed until the chronicity of the temperature is well established This direction may sound ambiguous, but it entails an absolute certainty that the general well-being of the child is not suffering as a result of the infection which is responsible for the rise in temperature If there is progressive loss in weight or failure to gain, or if a secondary anemia develops which does not improve, absolute rest in bed is indicated Otherwise, after two or three weeks' observation, these children should be gradually gotten up, following the scheme previously described in the treatment of the malnutrition type of case, and, eventually, in spite of their slight rise in temperature, which may last for months, they should be allowed to lead their normal lives and attend school

The thermometer should be discarded because, if it is not conducive to the development of a neurosis in the child, it is in the mother, which is quite as serious These children should, however, be seen by their medical advisers often enough that the latter may be certain that the chronic infection is in no way interfering with the general progress, the best criterion of which is normal gain in weight Nothing beyond the general measures previously recommended can be advised in the treatment of the asthmatic type of bronchial lymphadenitis except the use of bacterial proteins, the specificity of which has been determined by previous skin tests

CONCLUSIONS

1 Simple bronchial lymphadenitis, acute, subacute or chronic, is a distinct clinical entity in childhood

2 It may be divided into five definite types, based on the clinical history and cardinal symptoms 1 Malnutrition type 2 Subacute bronchitis type 3 Pertussoid type 4 Chronic febrile type 5 Asthmatic type

3 When one considers the great incidence of respiratory infection to which bronchial lymphadenitis is secondary, the general conclusion can be reached that this type of disease, in contrast to tuberculosis, is the most common disease of the bronchial lymph nodes

4 The diagnosis must be made by a combined consideration of the history, physical signs and roentgen-ray interpretations

5 The most important question for differential diagnosis is the possible presence of tuberculosis, which can be established by the use of tuberculin

6 The treatment may be briefly summarized under three heads rest, fresh air and diet

7 With accuracy in diagnosis and careful observation in the details of treatment, the prognosis is invariably good, unless a secondary infection takes place with the tubercle bacillus

MEDICOLEGAL APPLICATION OF THE BLOOD GROUP

J ARTHUR BUCHANAN, M D
PUEBLO, COLO

The danger of using the blood group as a means of determining parentage in cases of suspected or known illegitimacy arises from the difficulty in establishing the origin of the particular blood group in each instance The danger rests solely in the transmission of an unexpected blood group through the germ plasm of a heterozygous parent The heterozygous status of a parent cannot be foretold today, except by a study of the offspring

The criteria established by Ottenberg [1] to govern the medicolegal application of the blood group are incorrect in some instances, and based on insufficient evidence in others They would lead frequently to the miscarriage of justice when applied by a court in the adjustment of a dispute concerning parentage The families used by Ottenberg in formulating his criteria are too small in most instances to justify any conclusions

Ottenberg has established certain definite laws in connection with the blood group by means of which he contends that the legitimacy of children can be determined

1 If a child is in Group II, III or IV, when its parents are both in Group I, the child is illegitimate

2 In unions of Group I and Group II if a child is in Group III or IV, it is illegitimate

3 In unions of Group I and Group III if a child is in Group II or IV it is illegitimate

RESULTS OF CROSSING GROUP I WITH GROUP I

In a previous communication [2] on this subject, I published eight charts, which were representative of eight actual families The blood of the families was grouped by myself The Moss classification was used The Group I of Jansky is the Group IV of Moss The blood group of the family represented in Figure 1 of my previous paper, when classified according to the Jansky classification, shows, although both parents are in Group I, that there are two children who are in Group III, and four children who are in Group I At that time I had completed grouping the blood of a family in which by the Jansky classification both parents are in Group I, but their twin daughters are in Groups I and II Somewhat later, in grouping the blood of the Tink family,[3] I discovered two parents in Group I of the Jansky classification Three of their children are in Group IV, and one child is in Group I

In a family whose blood I have grouped, both parents are in Group II, but three of their children are in Group II and one child is in Group I The grouping of the blood of the grandparents in this family shows that the Group I could have arisen from either the maternal or the paternal side, as the parental stem on both sides consists of a cross between Groups I and II

MEDICOLEGAL SIGNIFICANCE OF THESE FINDINGS

The first law of Ottenberg is invalid, as unions of Group I can result in children whose blood may be in

1 Ottenberg Reuben Medicolegal Application of Human Blood Grouping J A M A **77** 682 (Aug 27) 1921 Hereditary Blood Qualities J Immunol **6** 363 (Sept) 1921 Medicolegal Application of Human Blood Grouping J A M A **78** 873 (March 25) 1922

2 Buchanan J A Medicolegal Application of the Blood Group J A M A **78** 89 (Jan 14) 1922

3 Buchanan J A A Consideration of the Laws of Heredity and Their Application to Various Conditions in Man to be published.

Group I, II, III or IV It is clear, since a Group I crossed with a Group I gives rise to groups other than itself, that it is unreasonable to contend that a Group I crossed with a Group II or Group III should not result in children in either Group I, II, III or IV The groups possible in the offspring of any union depend on the groups present in the previous generations, and the heterozygous or homozygous status of the parents of the generation under consideration

The blood groups possible from unions of Group III with Group III are undetermined, as there are not sufficient families on record in which this cross has been studied to justify any statements From a study of the families in which it has been found that unions of Group II may result in children in Group I, and that unions of Group I may result in children in Group II, the suspicion has been aroused, since Group I parentage may transmit a Group III to the children, that Group III parents may transmit a Group I to the children More crosses of Group III with Group III must be studied

SIGNIFICANCE OF THE FAILURE OF THE CRITERIA OF OTTENBERG

The criteria of Ottenberg are built up on the belief that unions of Group I can breed only Group I children, and, when that belief is shown to be false, the theory on which he based his conclusions becomes untenable The theory is still more erroneous in light of the knowledge of the segregative properties of the germ plasm Ottenberg contends, as do many others, that Group IV is the result of the union of certain specific substances on which Groups II and III depend If this theory is correct if the blood group is hereditary, and if the theory of heredity is correct, all unions of Group IV, because of the segregative function of the germ plasm, would result in children who are in Group IV, Group II and Group III, as happens in the second filial generation of all plants, fowls and animals in which an hereditary character has been studied The fundamental factors which enter into the make-up of the parents are segregated in the children Unions of pure Group IV are on record

The incorrectness of the statement of Ottenberg[4] that he could foretell the parents by studying the children resulting from unions of Groups IV and I is shown in the seventy-second family of von Dungern and Hirschfeld, the twenty-ninth and thirty-eighth families of Learmouth,[5] and in the Tink family[3] of my own investigation The union of pure Group IV and pure Group I of the Jansky classification results in children in Group IV and Group I, in the ratio of three of the former to one of the latter Unions of heterozygous Group IV and heterozygous Group I result in the reappearance of the groups present in previous generations, as well as those present in the parents of the children under investigation, provided there are a sufficient number of children to permit of all the possible groups being segregated

The entire data concerning the families on which my conclusions are based will be published in the near future[3] Each family is uninvolved by any question of illegitimate children My findings are in accordance with all the results of studies of the blood group in families that have been published, but by using a fairly fixed standard sized family, and by carrying the grouping into the third generation and even into the fourth, I was able to determine what groups might occur from most of the possible crosses of the blood group The results show the fallacy of the theories concerning the two specific substances on which the blood group has been supposed to depend The interesting studies of Learmouth show that the old theory of the two specific substances for the blood group and the mendelian inheritance of the blood group are at variance The blood group is either not hereditary, or the laboratory experiments concerning the specific substances responsible for the blood group are being misinterpreted The blood group follows in its transmission between generations the two laws of Mendel

SUMMARY

The criteria of Ottenberg to govern legitimacy by means of the blood group are dangerous The blood group cannot be used in the adjudication of medicolegal disputes concerning parentage without carrying the grouping back at least three generations, and even then there exists the possibility, because of the heterozygous status of a parent, of an unexpected, yet legitimate, group appearing without its definite origin having been determined

OBSERVATIONS ON THE ETIOLOGY AND PATHOLOGY OF CHOREA MINOR*

LOUIS C SCHROEDER, M D
NEW YORK

Far reaching as have been the advances in modern methods of clinical and laboratory investigation, it cannot yet be said that a definite answer has been found to the problem of chorea minor To the older physicians it was a functional disorder of the brain, while to a younger generation, it may be of an infectious, a rheumatic, an organic, a toxic or even a syphilitic origin Evidence may easily be found to support any of the above theories

The disorganizing confusion which arose from classifying as chorea every morbid process which had as a distinguishing feature athetoid, bizarre or purposeless movements has, happily, long since been dispelled To that extent our problem is easier, but much unexplored ground remains to be covered before we can truthfully say what the actual causative factor is and what pathologic processes ensue

In discussing the pathology of chorea minor, Poynton and Paine[1] emphasize the fact that we must not be satisfied with the plain statement that chorea minor may be the first manifestation of acute rheumatic fever but must actually link them together as part and parcel of the same process They further state that it will be a distinct advance in our knowledge when the answer to this is finally determined

A step forward was made when Aschoff described the so-called submiliary nodules of rheumatic fever These, it may be recalled were focal lesions, most frequently found in the walls of the left ventricle and characterized by fan-shaped collections of giant cells,

* From the New York Nursery and Child's Hospital and the Department of Pediatrics Cornell University Medical College
* Read before the Section on Diseases of Children at the Seventy Third Annual Session of the American Medical Association St. Louis May 1922
1 Poynton and Paine Researches on Rheumatism London J and A Churchill 1913 p 257

recalling to some extent the giant cells of similar shape which Dorothy Reed has described in Hodgkin's disease

Besides these large cells, there are lymphatic and neutrophilic leukocytes as well as some containing eosinophil granules, concerned in the building up of the nodule These infiltrations of small cells are continued as streaks into the surrounding tissue The rheumatic nodules which are grouped around vessels are very small

In the great majority of all his cases of valvular disease, Aschoff [2] "found no fresh inflammation at all, but only more or less numerous perivascular fibrous nodules, which are, in all probability, to be regarded as the healed remnants of the rheumatic nodules"

Coombs [3] agrees that these submiliary nodules are food for much thought He believes that it cannot be doubted that they are inflammatory in type and represent the reaction of the connective tissue to an infection rather than an intoxication only, and that the infective agent itself comes in contact with the tissues at the points where the nodules form He examined a number of hearts from cases of pneumonia, malignant endocarditis and suppurative pericarditis without finding anything at all like an Aschoff nodule

Confirmation of these findings of Aschoff has been made by a number of observers abroad, especially Fraenkel,[4] who believes that, even in the absence of a history of rheumatic fever, the finding of Aschoff nodules is strong presumptive evidence of a preceding rheumatic infection Rothschild and Thalheimer,[5] in their conclusions, make the definite statement that in rheumatic myocarditis, foci, termed submiliary nodules of Aschoff, are present, which are characteristic of the rheumatic infection

Bearing this fact in mind, the following case report is of extreme interest

REPORT OF CASE

History—G R, girl, white, aged 20 months, was brought to the New York Nursery and Child's Hospital by her mother because of irritability and rapid breathing The parents were in good health, although the mother had had acute rheumatic fever involving both knees The maternal grandfather was reported as having had "rheumatism" One other child was alive and well, and there had been no miscarriages

The infant had been born at term, and the delivery was normal She had been breast-fed for one year and then put on the usual mixed diet Up to the present illness, her general health had been good

Six weeks before, she had become very irritable For three days fever was present, and the family physician made a diagnosis of sore throat with a secondary adenitis A throat culture was negative for diphtheria The irritability continued, though the other symptoms subsided

Five days before admission, the mother noticed that the child was breathing very rapidly, and for that reason brought her to the hospital

Examination—The salient features of the physical examination were a markedly enlarged heart, a systolic and an early diastolic murmur, a breathing rate of eighty a minute a greatly enlarged liver, a slightly enlarged spleen, a red throat, and a temperature of only 99 F

Fluoroscopic examination ruled out pericardial effusion and all disease of the lung

During the first six days in the hospital, the only changes noted in the physical condition were the development of an inconstant to and fro friction rub in the third left interspace, a slight diminution in the size of the liver and a slight edema of the face No petechiae were noted, there was no cyanosis and the blood culture was negative

The spinal fluid was clear and under no increased pressure, and no globulin was found The cells numbered 10 per cubic millimeter, and were all lymphocytes The blood examination revealed a leukocytosis of 25,000, with a differential count of 69 per cent polymorphonuclears 21 per cent small lymphocytes and 10 per cent large lymphocytes

It was the general opinion that we were dealing with an acute endocarditis and pericarditis, the origin of which was uncertain

Course—On the seventh day of her stay in the hospital, the patient developed a typical chorea minor, and the temperature, which had never gone above 100 F, rose to 101 5 F We are not insensible to the difficulties often attendant on the correct diagnosis of true chorea in infancy, and we shall obey Sturges'[6] injunction that every case thus diagnosed needs the guaranty of a full description

On the morning of the seventh day, it was noticed that the right arm was moved over the covers in a jerky purposeless, incoordinate manner Later on the same day, the movements were noted in the left arm The following day, both lower extremities were in a state of constant incoordinate movement The facial muscles exhibited peculiar grimaces and the shoulders were shifted about in an unmistakable manner They were not the restless movements of a sick child

These pronounced motor disturbances continued with varying severity until a fatal termination, three days later At no time were any subcutaneous nodules seen, and they were searched for diligently, nor was there at any time evidence of joint involvement

Pathologic Findings—Two blood cultures having been negative, we were forced to the conclusion that the case was one of true rheumatic carditis and pericarditis This diagnosis were borne out at necropsy for the heart and pericardium were both involved, the mitral valve showing a number of very small vegetations, while the pericarditis, which, as is well known, is almost always of a rheumatic type in childhood, was nonpurulent

Microscopic examination of the heart muscle revealed typical Aschoff nodule cells, although the arrangement of the majority of them was not fan nor rosette shape owing probably, to the short course of a fulminating infection

Unfortunately, permission to examine the brain could not be obtained

COMMENT

Since the middle of the last century, when Germain See first offered evidence that chorea minor and rheumatic fever were allied, and Roger, a few years later, grouped chorea, rheumatism and endocarditis together in the phrase "la choree rheumato-cardiaque," all pediatricians have had occasion to verify their conclusions Cheadle [7] quotes Trousseau as being the first to recognize a rheumatic sore throat, and, since that time, evidence has piled up which definitely links tonsillitis with rheumatic fever, and further proves that the sore throat as a rule precedes the acute attack

All of these observations do not explain the cases of chorea which give no sign of rheumatism These cases have been the great stumbling block to our full acceptance of the theory that chorea is mainly rheumatic in origin

The case reported, occurring at an age when both chorea and rheumatism are extremely rare, tends to strengthen the belief that sore throat should be looked on as a possible manifestation of rheumatic fever, and that chorea minor should be considered, at least in childhood, as definite evidence of a rheumatic infection

7 Cheadle W B The Rheumatic State in Childhood London 1889

The most recent advances in our knowledge of the pathology of chorea minor are undoubtedly due to the impetus given by a more correct understanding of the physiology of the basal ganglions Lesions of this area may certainly cause involuntary movements of the skeletal muscles, as has been shown by Hunt [8] Wilson's [9] earlier work also proved that many involuntary motor movements were due to a lesion in the corpus striatum

Another factor which has helped in our understanding of the pathology of chorea minor has been the interesting histologic studies of the brain in epidemic (lethargic) encephalitis Alfaro [10] believes that chorea is the result of the action of bacterial poisons on the basal ganglions, particularly the striate body He assumes that there is an encephalitis due to a rheumatic poison

One of the most interesting contributions is an exhaustive study made by Marie and Tretiakoff [11] of the nerve centers of a 10-year-old girl who died at the height of an attack of chorea They describe a typical encephalitis, involving to a slight degree the cortex, but showing marked and distinct changes in the corpus striatum The only condition from which their findings were indistinguishable was epidemic encephalitis

Schuster [12] reports four cases of chorea, in all of which the patients had an encephalitis, the chief lesions occurring in the thalamus and the red nucleus

These findings are distinctly helpful in localizing the major pathologic changes We may not agree that in the majority of cases such marked organic lesions occur, but it cannot be doubted that in those areas there are certain happenings which give us the typical picture of chorea minor

It is conceivable that an encephalitis may be of such a transitory nature that it leaves no permanent damage, but when we seek support for this theory in the spinal fluid we are distinctly disappointed, as the majority of investigators report negative findings

Quigley [13] has succeeded in getting positive cultures from both the blood and the spinal fluid in ten out of twenty-one cases and from either one or the other in fourteen cases There was no increase in the cell content, and the globulin findings were negative

Cobb [14] raises an objection to the organic theory, stating that there can be no doubt that chorea may follow fright or sudden emotion, but he asks the question whether or not an organic lesion, previously without overt symptoms, is suddenly able to be activated by an emotional shock He believes that the records of many cases go to prove that it must be considered a reasonable possibility, although the physiologic and pathologic mechanisms are not understood

If we accept the foregoing suggestion, which explains not only the cases of chorea minor due to shock but also those of chorea gravidarum, we are entitled to consider chorea minor as the manifestation of the action of toxins on the brain, particularly the basal ganglions

These changes may produce a mild epidemic encephalitis, which usually does not but may cause permanent organic changes, and, in certain individuals, especially females, leaves on the personality, as Cobb says, "such indelible impressions of mental anguish of having lived through a period of lack of motor control that if in later life, this individual is to have a psychosis, it may more easily take the form of chorea than any other type of symptomatology"

SUMMARY

Aschoff nodules have been demonstrated in the heart muscle of a 20-months-old child who had chorea and a fulminating rheumatic carditis and pericarditis

Advances in the study of the physiology of the basal ganglions make it seem likely that the chief pathologic changes in chorea minor occur there

39 East Sixty-First Street

ABSTRACT OF DISCUSSION

DR H F HELMHOLZ, Rochester, Minn The studies that have been made in large series of cases of encephalitis have thrown a great deal of light on the study of the so-called rheumatic cycle in its neurologic manifestations The definite localization in the basal ganglions in encephalitis, particularly those in the lenticular nucleus, has produced a syndrome which in the acute stage, is indistinguishable from what we call chorea It is interesting to note that in a great number of these cases the choreic manifestations persist for only a short time They seem to be only a transient stage We have observed this last year a number of residues of encephalitis involving the basal ganglions In about two thirds of these cases we have had a definite history of an attack of choreiform movements lasting usually for a period of several weeks and then clearing up the patient being perfectly well for a time and then having a secondary involvement which led ultimately to the so-called parkinsonian syndrome In chorea, we are unquestionably dealing with an infection and just as it is difficult to isolate the organism from the joints and heart valves so it is difficult to isolate the organism in the brain In the literature of encephalitis the world over, we find that many observers have been able to isolate organisms from patients who died of encephalitis, and have also been able to find those organisms in the area of inflammatory reaction So it is not surprising that it is difficult to isolate organisms in chorea There is no question that we are dealing with an encephalitis due to a specific organism which has a tendency to localize in the basal ganglions, but we also have very marked psychic disturbances which may indicate that there is involvement elsewhere It may be that these changes are the cortical changes described by Marie I wish to emphasize the importance of a careful histologic study of all cases of chorea that come to necropsy

DR H W CHENEY, Chicago Clinical experience bears out the fact that infections are the cause of chorea, and my habit has been to look for the focus of infection in all cases and I usually find it One point is that, while the tonsils may be responsible for some of the cases I have seen cases recently in which the only apparent sources of infection were bad cavities in the children's teeth and the removal of those teeth cleared up the disease promptly and well While the treatment was not brought out in the paper, bad cases of chorea can be controlled without the use of opium or bromids by administration of sufficient acetylsalicylic acid I give several doses daily up to 10 grains at a time That will control the involuntary movements

DR WALTER E SIMMONDS Chicago With regard to the use of acetylsalicylic acid in some experiments which are running parallel to the ones we did on arthritis in rabbits we found that when we gave acetylsalicylic acid, inflamed kidneys resulted So in the treatment of chorea I would hesitate to give this drug I find that these patients respond quite as well to the arsenical preparations

GASTRIC FINDINGS IN CHILDREN WITH ANOREXIA *

L W SAUER, M D, L D MINSK, M D
AND
W G ALEXANDER, M D
EVANSTON, ILL

Much has been accomplished during the last few years with the child who is chronically underweight for his height Through the efforts of Emerson[1] and others the relation of "malnutrition" to physical defects, improper food habits, overfatigue and errors of home and school life has been pointed out Many underweight children have been made "free to gain" by the removal of these handicaps

In our clinical work with the underweight child, we occasionally encountered children who, although rendered free to gain, failed to increase in weight on account of a persistent anorexia These children with poor appetite ate less than the required number of calories and were underweight because they ate insufficiently Physical and laboratory examinations showed them to be free from tuberculosis, anemia, physical defects, diseased tonsils, adenoids and other known causes of anorexia Their diets were like those on which our other underweight children thrived, containing an abundance of accessory food factors Cases of poor home environment or lack of cooperation of parent or child are not included All but three children had brothers or sisters who ate well They were given only three meals a day, avoiding excess of fats

‡ Date refers to gastric analysis roentgen ray examinations were made several days earlier

The present study deals with the gastric motor and secretory functions of two groups of children Group A, twelve normal children with good appetite, Group B, twenty-one more or less underweight, but otherwise normal, children with poor appetite

Observations were made on the former group in order to establish a basis for comparison Observations were repeated (*a*) in a number of subjects of both groups after a few days, (*b*) in most subjects of both groups after a lapse of several months

The early repetition was deemed necessary to detect any variations which might be due to technic or to individual variations which might occur from day to day The repetitions, some months later, served to show any variations which might occur after such a lapse of time, as well as changes which might occur when improvement had taken place

METHODS

The motor meal[2] consisted of 240 c c of warm milk, 30 gm of barium sulphate, 4 gm of sugar and two slices (45 gm) of white bread (without crust) These were well mixed, and fed at 9 a m , following a fast of about fifteen hours The entire meal was given within fifteen minutes Serial films were taken four hours later, and each succeeding hour, until the stomach was empty The pictures were taken with the subject prone on the cassette, with the tube at the back The subjects were kept more or less occupied with games and ordinary indoor activities, and were not permitted to take anything by mouth or to lie down (except for the roentgen-ray examination) until the examination was concluded

1 Emerson W R P Nutrition Clinic in the Public School Am J Dis Child 17 251 (April) 1919
2 This meal (except for the amount of barium sulphate) is recommended by the Royal Society of Medicine as standard for radiographic examination of the alimentary canal

A few days later, a test breakfast, consisting of five arrowroot crackers, 240 c c of warm water and 4 gm of sugar, was given at 9 a m, after a fast of about fifteen hours One hour after ingestion, the stomach was emptied with a Rehfuss tube, suction being applied with a syringe Aspirations were usually limited to about ten minutes Subjects were not permitted to take anything by mouth, nor to lie down until the aspiration was completed They were asked to expectorate freely and not to swallow saliva during aspiration

Total and free hydrochloric acid determinations were made on the mixed, unfiltered gastric contents according to the Toepfer [3] method

RESULTS

Serial roentgenograms on the twelve children with good appetite showed all stomachs empty within five hours with an average emptying time of four and one-half hours Similar motor function tests on the twenty-one children with poor appetite showed that their stomachs usually emptied much more slowly—in only one of the twenty-one children was it empty within the time found to be the average for the former group A repetition of the motor function tests within a few days in a number of subjects gave results which checked very closely

TABLE 3—SUMMARY OF THE FIRST SERIES OF MOTOR FUNCTION TESTS

	Number of Cases	Number of Cases in Which Stomach Emptied in								Average Emptying Time
		3½ Hrs	4 Hrs	4½ Hrs	5 Hrs	5½ Hrs	6 Hrs	7 Hrs	8 Hrs	
Group A (good appetite)	12	1	4	2	5					4 5 hrs
Group B (poor appetite)	21	1	0	0	4	2	5	7	2	6 1 hrs

Before our work had progressed very far, we noticed that many of the underweight children with anorexia belonged to the types Mills [4] so clearly describes as hyposthenic and asthenic We found the habitus of children to conform with the four types he found in the adult hypersthenic, sthenic, hyposthenic and asthenic Eleven of the twelve children with good appetites were of the sthenic habitus, whereas, only five of the twenty-one with poor appetites were sthenic, the other sixteen being hyposthenic or asthenic Mills shows that the person with the hypersthenic habitus has the most rapid gastric motility, the asthenic, the slowest—the stomach frequently not being empty six hours after the standard opaque meal

In Table 4, the original emptying time of the stomachs of seven children of Group A and thirteen children of Group B are compared with the findings a number of months later Seven of the children of Group B had improved in appetite and weight, as shown in Table 2

The hydrochloric acid determinations were usually performed from three to seven days after the roentgen-ray examinations In order to detect possible errors in technic or individual daily variations, these analyses were also repeated in a number of instances within a few days, with rather good agreement Duplicate acid determinations were always made After several months, the gastric analyses were repeated in the twelve children with good appetite and in twelve of the twenty-one with poor appetite Table 5 gives the averages of total and free acid at the first analysis

The most striking difference was found in the amount of free hydrochloric acid For the children with good appetite it averaged 26 3, for the children with poor appetite, 14 9 Hurwitz,[5] who has recently

TABLE 4—A COMPARISON OF THE ORIGINAL EMPTYING TIME WITH THAT FOUND SOME MONTHS LATER

	Number of Cases in Which the Stomach Emptied in								Average Emptying Time
	3½ Hrs	4 Hrs	4½ Hrs	5 Hrs	5½ Hrs	6 Hrs	6½ Hrs	7 Hrs	
Group A (7 cases)									
First examination	0	2	1	4					4 6 hrs
Later	2	1	2	1	1				3 6 hrs

worked with German children from 2 to 15 years of age found an average of 48 8 for total acid and 14 3 for free acid

In Table 6, the original and subsequent average acid findings of the twelve children with good appetite are compared with those of twelve of the children with poor appetite who were reexamined The appetite and weight of seven of the latter had improved

It will be seen that the average total and free acid for the former group was somewhat lower when determined a few months after the first analyses, whereas, the average total and the free acid for the children of Group B were higher at the subsequent examination Two of the children (Table 2, Cases 11 and 13) showed no free hydrochloric acid On reexamination some months later, free hydrochloric acid was still absent They had not improved

The gastric return varied from 40 to 140 c c, and averaged about 80 c c The amount of material recovered at the end of one hour bore no relation to the degree of acidity

DISCUSSION

While the habitus (relation of the general "build" to the topography of the viscera) predetermines to a marked degree the motor function of the stomach, our results show that even the child with the asthenic habitus and long emptying time can so improve that the time is markedly shortened Carman [6] says, "The function of the stomach is in proportion to the degree

TABLE 5—SUMMARY OF SECRETORY FUNCTION

	Number of Cases	Average Acidity	
		Total	Free
Group A (good appetites)	12	61 2	26 3
Group B (poor appetites)	18	49 4	14 9

of asthenia present, and the greater the asthenia, the poorer the tonus and the longer the time required for the stomach to rid itself of its contents" Kerley [7] points out that one of the pronounced effects of delayed emptying is a loss of appetite, and that a child will not be hungry with a portion of a previous meal in the stomach In our first series of examinations, all of the children with an emptying time of five

3 Hawk Practical Physiological Chemistry Philadelphia P Blakiston's Son & Co 1916
4 Mills R W Am J Roentgenol 4 155 (April) 1917

or more hours (twenty of the twenty-one) had very poor appetites, and sixteen were hyposthenic or asthenic The influence of a few months of careful supervision in seven of the thirteen children with poor appetites who were reexamined is reflected in the shortening of emptying time (Tables 2 and 4), increase in the amount of hydrochloric acid (Tables 2 and 6) and increase in their appetites and weights The two children without free hydrochloric acid (Table 2, Numbers 11 and 13) were of the asthenic habitus, but had no delayed emptying times They failed to improve in spite of treatment The seven children with poor appetite who improved after several months show that the motor and secretory function can be improved by simple measures

TABLE 6—COMPARATIVE STUDY OF GASTRIC SECRETORY FUNCTION

	Number of Cases	Average Acidity	
		Total	Free
Group A (good appetites)			
First examination	12	61 2	26 3
Later	12	55 1	22 3
Group B (poor appetites)			
First examination	12	43 5	12 1
Later	12	60 6	19 0

Our observations lead us to conclude that children of the hyposthenic and asthenic habitus are much more likely to have poor appetite slow emptying time and low free acid than are those of the sthenic habitus, but that the emptying time can be shortened, and the hydrochloric acid, appetite and weight increased by proper measures

SUMMARY

1 The average emptying time of the stomach for twelve children with good appetite was four and one-half hours, that for twenty-one children with poor appetite was six and one-tenth hours The stomachs of the twelve children in Group A were empty in five hours, while sixteen of the twenty-one of Group B still had retention at the end of five hours

2 All but one of the twenty-one children with poor appetite had an original emptying time longer than that found to be the average for the children with good appetite

3 The average total hydrochloric acid for the twelve children with good appetite was 61 2, the free acid 26 3, for eighteen with poor appetite, the total acid was 49 4, the free acid 14 9

4 In two children of the group with poor appetite, free acid was absent on examination and on reexamination months later, while their emptying times were not especially long

5 Eleven of the twelve children of the former group were of the sthenic habitus Sixteen of the twenty-one children of the latter group were of the hyposthenic or asthenic habitus

6 In a number of asthenic children, the emptying time of the stomach and the amount of acid were influenced beneficially by proper measures, and this was reflected by an increase in appetite and weight

ABSTRACT OF DISCUSSION

DR W MCKIM MARRIOTT, St Louis Dr Sauer's paper is interesting, as it points out that there is not such a great deal of difference in the physiology of digestion in children and in adults The paper is important because it points the way to the treatment of certain types of digestive disturbances in children A number of deductions may be drawn from Dr Sauer's paper, and some of these he has already mentioned His results make very evident the fallacy of attempting to build up these malnourished children by stuffing them with food at frequent intervals, so that the stomach never has time to empty completely Furthermore, in children of the type described, who are suffering from a deficit of hydrochloric acid, it is a mistake to give large amounts of cow's milk, as this food, more than any other, neutralizes the acid in the stomach Cow's milk will neutralize about an equal volume of tenth-normal hydrochloric acid We have recently been interested in the gastric secretion in infants, and our results are in entire accord with those of Dr Sauer with older children Malnourished infants who fail to gain and have a poor appetite often show marked deficiency in the hydrochloric acid of the stomach We have found also that infections of any sort were likely to result in decreasing the acid secretion I should like to ask Dr Sauer if he has studied the effect of infection on the children studied by him

DR LEON T LEWALD, New York This work is exceedingly valuable and fits in with observations on younger children, young infants and young adults In regard particularly to the emptying time of the stomach from the roentgen-ray standpoint I am glad that Dr Sauer gave his exact technic as to the quantity of food ingested, and while I find that this is not of great importance, as we have tried out various types of feedings and even the ingestion of a simple watery suspension of barium yet the quantity given by him to a child of the age stated gives us something to go on in future studies Also, I am glad to see that he checked his observations later I should like to ask him two questions First if he has any explanation for the increased weight and appetite of the children? It has been suggested that the roentgen ray does stimulate the gastric and intestinal glands, and it is not unusual to find a few months after roentgen-ray examination that these persons have decidedly improved The second question Did he observe any other pathology than the slow emptying of the stomach to account for the condition of anorexia? In other words, did he find pyloric obstruction or pylorospasm or lesions farther down in the digestive tract, such as redundant conditions in the colon, that might account for the slow emptying of the stomach reflexly?

DR JOHN A FOOTE, Washington, D C Dr Sauer has made a very valuable contribution to what we know about nutrition in the older child The scattered cases which do not respond to treatment and which show no other physical reason for not gaining are explained in a way There are so many factors which have to do with the gain or loss of weight in the older child that it sometimes seems impossible to check up and correlate all of the conditions which might have an influence on the metabolism or the organization of food Dyer of London is more impressed with improvement in the vital capacity of the child as a factor in improving weight I wondered on hearing this paper whether Dr Sauer had made any observations on the history of these children—what the heredity might have been, and what the earlier history might have been Some years ago Dr Abt spoke of the nervous type of infant the same type which has been described by Heim, who found that many of these had hyperacidity and belonged to the pylorospasm group These children were very energetic and of neurotic parents, and as they grew older they were a matter of great concern to the family They were neurotic and developed reactions to food, which showed bad adjustment to environment They acquired food likes and dislikes, and sometimes insisted on having foods that did not agree with them, such as meats and sweets It is quite possible that children who exhibit anorexia, impaired motor function and lowered hydrochloric acid, might have belonged to this hypertonic group in earlier life, that there might have been both a congenital condition and improper handling which resulted in the accentuation of the degree in which the children remained undernourished The earlier treatment of such children should be psychologic—the prevention of negativism, and especially these little tryants should not be allowed to learn that they can intimidate the household by refusing foods

DR. PARK J WHITE, St Louis Dr Marriott has mentioned the application of what Dr Sauer has said to chemical findings in infants Dr Sauer's remarks about gastric and intes-

tinal motility in older children may also be applied to certain conditions in infancy Dr LeWald mentioned pylorospasm in infants When there is pylorospasm, there is in all probability also enterospasm It is commonly accepted that the whole thing is probably due to overactivity of the vagus, which explains the good effects obtained with atropin The condition should really be called pyloro enterospasm In such cases, once the vomiting has been overcome, and with it the starvation and constipation, the food is hurried through the intestines, and thus once the pylorus has been passed, the intestines empty with considerable rapidity These infants undoubtedly require more food than normal infants do

DR ALFRED L KASTNER, Milwaukee In regard to older children with poor appetites, I see no other conclusion to arrive at than that the three hour feeding interval is a common cause The school child eats at 7 a m, comes into school and has a glass of milk at 10 o'clock and then has lunch at 12 Now, in children who are properly nourished, why impose such an extra load? It is true the child needs the extra food, but is he able to handle it in three-hour intervals?

DR LOUIS W SAUER, Evanston Ill I am sorry not to have made observations on older children with poor appetites during illness, fever and infections Of course, it is a well-known fact that infants in hot weather secrete less free hydrochloric acid than on cold days I agree that it is not a good thing to give these children milk between meals Children who will not eat breakfast should not be expected to drink milk between breakfast and the noon lunch I am not speaking of the child with good appetite who is underweight I am sorry not to have mentioned the work of Drs LeWald and Kerley Dr Kerley, a year ago, pointed out that one of the pronounced effects of delayed emptying time is loss of appetite and that a child will not be hungry with a portion of a previous meal in the stomach In one of his cases, the stomach was not empty for thirteen hours If such a child eats breakfast at 8 a m, and something is still in the stomach six hours after that, it will not eat a hearty lunch In regard to Dr Foote's question—sixteen out of twenty-one were of the asthenic habitus The significance of habitus is greatly neglected in pediatrics Many children who are frequently ill belong to the "slender" type The stomach is normally below the umbilicus Roentgenologists show that normal stomachs of this type may have an emptying time not of four but of six hours For that reason they set up six hours as the normal emptying time Normal persons of this type may have a long emptying time Children who come into this group are not children who have food dislikes With regard to the treatment we made the children "free to gain," fed them on foods rich in vitamins (lettuce sandwiches, carrots, spinach and, at times, cod liver oil) and tried to get them to take a quart of milk a day giving 8 or 10 ounces at each meal If we found the hydrochloric acid low we gave 1 dram of essence of pepsin with 3 drops of dilute hydrochloric acid with each meal The two children without free hydrochloric acid are interesting in that neither of them showed free hydrochloric acid in spite of the administration of 3 drops of the dilute hydrochloric acid for a period of several months

---

Preparation of Chaulmoogra Oil Derivatives—The working details of methods used at the University of Hawaii for the preparation of certain derivatives of chaulmoogra oil are described by Dean and Wrenshall in *Public Health Reports* June 9, 1922 The chaulmoogra oil used is obtained through dealers, and varies greatly in quality some lots being clear and liquid at laboratory temperature, other lots being dark muddy looking oils with large quantities of precipitated material The differences in appearance seem to have no correlation with differences in rotation of polarized light which is the distinguishing characteristic of these oils The valuable oils show specific rotations around plus 50 degrees The first step in the preparation of derivatives for therapeutic use is to break up the glycerids into glycerol and the sodium soaps of the fatty acids by saponifying the oil with sodium hydroxid under pressure These crude mixed fatty acids are then treated in different ways, the details of which are given as noted, and the following products obtained (1) mixed ethyl esters, (2) ethyl hydnocarpate, (3) ethyl chaulmoograte, and (4) ethyl dihydrochaulmoograte

THE QUINIDIN TREATMENT OF AURICULAR FIBRILLATION*

WALTER W HAMBURGER, M D
AND
WALTER S PRIEST, JR, M D
CHICAGO

Since the report by one of us (W W H[1]) in December, 1921, of eight cases of auricular fibrillation in which quinidin sulphate was administered, we have observed and treated ten additional cases In this paper we shall present (1) a further study of the cases previously reported, (2) the details of treatment and observation in ten new cases, and (3) the results and conclusions obtained from our experience with these eighteen cases in connection with a critical survey of the literature up to the present time

In spite of lack of complete knowledge of the pharmacology of quinidin, its indications and contraindications in practice, and the occasional reports of serious untoward effects (paralyses, embolism and death), interest in its therapeutic use continues to grow Reports and studies in quinidin therapy have appeared so fast during the past year, especially during the past six months, that it is well-nigh impossible to keep up with the constantly growing literature on the subject One gets the universal impression that, in spite of the accidents referred to above, it is rapidly establishing a place for itself in modern cardiac therapy Appreciating that our knowledge of the drug is as yet most incomplete, it must be borne in mind that its use in auricular fibrillation dates back only four years, since Frey's[2] work in 1918 It is interesting in this connection to reflect, as Jackson, Friedlander and Lawrence[3] have recently pointed out, that "Witherington introduced digitalis in 1783, while the year 1922 finds us still willing to learn more than we at present know about the foxglove"

Before presenting our own cases, it may be worth while to review very briefly the subject itself and its present status Auricular fibrillation, the most frequent serious irregularity of the human heart, may be converted, in approximately 50 per cent of the cases, to a normal cardiac mechanism by the administration of quinidin, one of the four better known alkaloids of cinchona bark, a stereo-isomer of quinin In a recent compilation of the literature by Oppenheimer,[4] in a total of 461 reported cases, 53 per cent of the patients were restored to a sinus rhythm Of our series of eighteen cases, eleven patients (61 per cent[5]) have secured, for a time at least, a normal rhythm, and in five (27 per cent) it has lasted three months or more The introduction of quinidin in the therapy of auricular fibrillation dates from Wenkebach's[6] accidental dis-

covery of the use of quinin in 1914 and Frey's work in 1918, at which time he showed the greater suitability of quinidin Since this time a large number of papers have been contributed on this subject and have served to throw considerable light on the exact mechanism, indications and contraindications, dangers, mode of action and selection of cases

CASES PREVIOUSLY REPORTED

Our first eight cases, reported last year, have been kept under observation, and the patients have reported back from time to time for examination and treatment

* For sex ♂ indicates male and ♀ female

Table 1 shows in brief the details of these cases As stated in our original paper, only four of these eight patients (50 per cent) secured a normal cardiac mechanism, and only one of the four has maintained a normal rhythm for any considerable period (eleven months) The remaining three, in spite of various dosages and combinations of quinidin and digitalis, have experienced frequent returns of fibrillation so that, finally, quinidinization was discontinued, as no permanent benefit could be secured Patient 2 has died, eight months after treatment, from increasing intoxication from his diabetic gangrene Patient 4, with hyperthyroidism (metabolic rate 51 8 +) is at present undergoing roentgen-ray treatment for his thyroid hyperfunction with the expectation that, when this is controlled, quinidin therapy will be more effective

The four cases that failed to respond to quinidin were all cases of advanced heart failure and have continued to pursue a progressively downward course One patient has died, the remaining three are seriously handicapped in their cardiac reserve and in their ability to carry on sustained activity

Summarizing our experience with our first group of cases after an interval of one year, it must be stated that the results are not particularly gratifying, as only 50 per cent of the total number of cases responded, and in only 25 per cent of these, or 12 5 per cent of the whole, has there been a permanent result Patient 1, whose sinus rhythm has persisted eleven months, underwent in March a gynecologic plastic operation necessitating a general ether anesthetic, lasting one hour, with no evidence of return of fibrillation It may be recalled that this patient, at the time of the restoration of normal rhythm, showed a disappearance of right heart preponderance with coincident relief of clinical signs of heart failure

NEW CASES

The new cases which we have to report comprise ten Seven of these (Tables 2 and 3) responded to quinidinization with the establishment of a normal rhythm, three cases were not responsive Of the seven responsive cases, three have maintained a normal rhythm for three months or more, the remaining four have had one or more recurrences of fibrillation Three may be classified as acute auricular fibrillation undergoing their first attack of irregularity, and three as recurrent paroxysmal fibrillation The contributory causes that were probably important etiologically were acute respiratory infection, paratyphoid fever, pneumonia menopause, hypertension, toxic goiter and generalized arteriosclerosis The duration of the fibrillation varied from a few hours to several weeks The amount of quinidin necessary to control varied from 0 2 to 3 8 gm , the total amount of quinidin administered to any one patient was 23 2 gm While it is well known that the paroxysmal type of fibrillation often ceases of its own accord, these cases were so controlled that it appeared likely that the restoration of sinus rhythm was brought about as a result of

quinidin administration It is probable, too, that the drug materially shortened the paroxysm of irregularity, for in one and the same case, in which for various reasons certain attacks were allowed to continue untreated, the giving of quinidin was promptly followed with a restoration of normal cardiac mechanism Four of these seven cases were private cases under careful and repeated observation and control and, with the patients' intelligent cooperation and insight into their own problems, they themselves were convinced of the controlling action of quinidin One of them, a physician administered the capsules to himself and controlled the paroxysms of irregularity largely at his own discretion

There is little to be said regarding the three cases of auricular fibrillation which failed to respond to quinidin In contrast with the nonresponsive cases of the first series, none of them were cases of advanced heart failure, although one was classified as moderately advanced and the others early heart failure In one case, quinidin was discontinued after a dosage of 8 4 gm, covering a period of eight days, because of complaints of spots before the eyes, dizziness and ringing in the ears In a second case, after 12 gm had been given, quinidin was discontinued because of the production of a bradycardia varying between 40 and 52 apex beats a minute One or two other of our patients have experienced a similar bradycardia Curves of this patient showed a continuance of the high auricular rate with the very slow ventricular, suggesting that in large amounts over a prolonged period, quinidin does affect the auriculoventricular bundle, producing a rather high degree of partial heart block The effect of quinidin direct on the heart muscle and on the vagus must also be considered in this connection These patients, in spite of showing evidence of heart

failure, were all cases of relatively long fibrillation, so that we conclude that this factor is probably of greatest constancy in the nonresponsive cases

Rather than present the details of these cases, we shall discuss certain of the more important and obscure problems in connection with a critical survey of the literature up to the present time We shall discuss these in this order (1) favorable cases and indications for quinidin therapy, (2) unfavorable cases and contraindications, (3) dosage and method of administration, (4) digitalis, (5) subjective symptoms, clinical value, effects on compensation and decompensation, (6) toxic effects, accidents occurring during administration, respiratory paralysis, skin lesions, (7) effect on auricular and ventricular rate, vagus, venous, arterial and pulmonary pressure, peripheral vessels, (8) changes in P-R interval, QRS complex, T wave, heart block

FAVORABLE CASES AND INDICATIONS FOR QUINIDIN

It is generally agreed that patients with fibrillation of short duration and with relatively good heart muscle, with no signs of decompensation, are most favorable for the administration of quinidin Bock[7] and Chemisse[8] believe that it is particularly valuable in patients with hyperarterial tension and with peripheral arteriosclerosis Wolferth's[9] case of hyperthyroidism showed the most striking improvement Pardee[10] inclines to patients with relatively good heart muscle and fair compensation Our best results have been obtained in the acute and paroxysmal varieties, although our instance of restored sinus rhythm of longest duration occurred in a chronic case in which fibrillation had been present for three or four years Our two hyperthyroid cases responded easily to small amounts of the drug, but quickly relapsed to fibrillation, although one of them could be controlled for weeks at a time with daily small amounts of quinidin (Fig 1) We are hopeful that reducing the hyperthyroidism by roentgen-ray treatment will result in a more permanent cure Our experience with patients with peripheral arteriosclerosis is that, while they respond promptly, they relapse equally so, and permanent results are difficult to obtain

UNFAVORABLE CASES AND CONTRAINDICATIONS

The literature is fairly in agreement in the fact that the most unfavorable cases are those of long duration with moderately advanced or advanced heart failure Our experience is in accord with this, although there are many exceptions to it Ellis and Clark-Kennedy[11] believe that those which do not respond to digitalis will not respond to quinidin Smith[12] believes that patients with large hearts are unfavorable Jackson, Friedlander and Lawrence, from results with experimental aconite poisoning, suggest that there may be two types of fibrillation, the early aconite poisoned animals responding, the late not White[13] believes heart failure and long duration are unfavorable cases Bock and Chemisse speak of acute and recurrent endocarditis as contraindications Thomas Lewis[14] warns against patients in whom there is any history or findings of previous embolism and patients with advanced heart failure as evidenced by an engorged, tender liver and dilated veins of the neck While we have been fortunate in experiencing no serious mishaps, we share in general the statements of the foregoing observers However, it is certainly difficult to predict whether a given case will be successful or not, although, in general, we now feel fairly safe in stating that the case with a single acute attack or a recurrence can usually be controlled promptly with quinidin

DOSAGE AND METHOD OF ADMINISTRATION

All observers are using practically the same amounts of quinidin, varying from 0 2 to 0 4 or 0 6 gm, three or four times a day Lewis recently spoke of using as a test dose 0 8 gm, the largest amount of which we know In general, we are using frequent small doses, and find that they are as advantageous as the larger amounts In a few recent cases we have omitted the preliminary idiosyncrasy dose, starting with 0 2 gm every two hours with careful, frequent examinations of the patient, and find that many attacks can be controlled immediately in from two to twelve hours by this method If such dosage is ineffectual, after a three or four day attempt, we increase the amount to 0 4 gm every two hours In our last cases we have been accustomed, after the establishment of sinus rhythm, to continue giving 0 2 gm once or twice a day for a considerable period, decreasing only gradually, believing, with Lyster and Fahr,[15] that, since in most

cases the conditions tending to produce auricular fibrillation are still present even after a normal rhythm is restored, subsequent administrations of the drug are necessary to avoid recurrence If stoppage of the drug is followed in a short time by a relapse, we start a second series of quinidin administration, continuing it practically indefinitely, meanwhile making every possible attempt to diagnose and treat the probable underlying causative disease It is remarkable how long and uneventfully patients can take small amounts of quinidin Several of our patients are continuing now in their second and third month taking one or two capsules (0 2 gm) a day without apparent harm

DIGITALIS

The role of digitalis has been and continues to be a much discussed one Pardee believes there is no effect either way from its administration Wolferth had an interesting experience in which the administration of digitalis was effective in restoring a sinus rhythm temporarily, later, quinidin was not successful Robert Levy [16] believes that digitalis is not essential to successful treatment Fred Smith feels that it is contraindicated, as both digitalis and quinidin may produce heart block White concludes that digitalized cases are more likely to respond, but that it is better not to give the two together Lewis believes that there is little difference in the auricular response, although possibly the undigitalized cases may be a shade more likely to respond than the digitalized, but he strongly feels that digitalis effects are desirable, especially in the rapid type of fibrillation, and shows graphically in one and the same patient the relative slowing of the ventricular rate in the digitalized cases We have had three interesting experiences To one patient, in whom, in spite of evident decompensation (cyanosis and orthopnea) digitalis was certainly indicated, we gave quinidin first without digitalis, and a prompt restoration of sinus rhythm occurred, with a simultaneous disappearance of signs of heart failure The second case, reported last year, showed without digitalis and with small amounts of quinidin a clearing up of early heart failure and disappearance of evidences of right heart embarrassment (right preponderance) In the third case, an exophthalmic goiter patient with an extremely rapid type of fibrillation, we had great difficulty in maintaining, without digitalis, a normal rhythm for more than a few hours until a time when he was completely digitalized, after which the same or even smaller amounts of quinidin were successful in holding his heart regular for three weeks As a result of these experiences, our practice at present is to give quinidin at once in a properly selected case without preliminary digitalization, in spite of a moderately rapid heart and signs of early or moderately advanced heart failure If, on securing a normal rhythm, the ventricular rate remains over 100, or if the signs of heart failure have not disappeared entirely, or if the restoration of a regular pulse is of short duration with frequent and early tendencies to relapse, we then digitalize the patient in the usual way

SUBJECTIVE SYMPTOMS, CLINICAL VALUE, EFFECTS ON COMPENSATION AND DECOMPENSATION

The symptoms mentioned most frequently in the literature as due to the administration of quinidin are palpitation, weakness and dizziness, dyspnea, oppression and tachycardia A few have noticed epigastric distress, ringing in the ears, headache, nausea, hemoptysis and hot flashes Some of these complaints have been voiced by our patients, others have noticed no subjective effects of any sort

From the standpoint of the effect on subjective complaints, that is, the value of the treatment from the patient's standpoint, the literature contains such statements as "no striking change", "no more than ordinary rest and diet", "relief experienced in slow type of fibrillation", "relief from palpitation", "general improvement" Lewis makes the interesting observation that, although several of his patients showed no immediate improvement and experienced no immediate change with restoration of normal rhythm, they experienced later improvement in strength, in general well-being and in ability to carry on In our experience, the private cases have experienced decidedly more personal satisfaction from the change than the ward cases, not only patients with exophthalmic goiter but also those with acute fibrillation following infection, they are extremely grateful when the irregularity has been stopped Our easy-going, phlegmatic patients noticed little if any change, our nervous, apprehensive, frightened ones were intensely frightened during the attack and strikingly relieved when it was over, and insisted on having their capsules near them day and night One patient with goiter, whose attacks often come at night, puts his capsules at his bedside and helps himself when his attacks rouse him from his sleep

Several men have reported that quinidin caused decompensation in a previously well-compensated fibrillating heart, or, at least with the restoration of sinus rhythm by quinidin, decompensation occurred We have fortunately had no such experience

TOXIC EFFECTS, ACCIDENTS OCCURRING DURING QUINIDIN THERAPY (EMBOLISM), RESPIRATORY PARALYSIS, SKIN LESIONS

Wilson and Herrmann [17] group the accidents occurring under quinidin therapy under six headings (1) increased cardiac failure, (2) apparent respiratory paralysis, (3) embolism, (4) failure of the sinus node to resume function, (5) depressed intraventricular conduction, (6) increased ventricular rate Embolism is, of course, the most serious, has resulted in several sudden deaths, and has caused infarcts in the kidney, lung spleen and brain It has caused transitory paralyses

We have been fortunate up to the present time in having no embolic cases, at least none that we recognized We have had several scarlatiniform rashes, dizziness and ringing in the ears, spots before the eyes, and sudden rise of temperature to 101 6 with severe headache, diarrhea and abdominal pain Such results as these are frequent findings throughout the literature The less serious findings are undoubtedly cause for immediate discontinuance of the drug We fully agree with Sir Thomas Lewis that any evidence of embolism is an absolute contraindication It is striking that several clinics report a much greater number of these accidents than others In this connection, it might be recalled that embolism is not an infrequent occurrence in fibrillation without quinidin, witness the reports of paralysis, infarcts, hemoptysis, etc, in the older literature

EFFECT ON AURICULAR AND VENTRICULAR RATE, VAGUS, VENOUS, ARTERIAL AND PULMONARY PRESSURE, AND PERIPHERAL VESSELS

Acceleration of the ventricular rate (ventricular tachycardia) is a frequent experience in patients undergoing quinidin treatment Drury and Iliescu,[18] by using sternal leads, have shown clearly the progressive depression of auricular rate, falling sharply from a single dose and only very gradually resuming its original rate We have taken sternal leads in connection with the regular leads in a number of cases, and have estimated the auricular rate (Fig 3) Table 4 shows the typical result of such estimation, showing

TABLE 4—REGULAR AND STERNAL LEADS CASE II

Date	Hour	Leads	Auricular Rate	Ventricular Rate	Rhythm
3/7/22	8 p m	Regular before quinidin	461 (approx)	171	Irreg (fibrillation)

	4 30 p m	Regular	75	75	Normal (S R)

the gradual depression of an original auricular rate of 460 during fibrillation to 260 during flutter, and finally to 75 with the restoration of sinus rhythm In contrast to Lewis' findings, the ventricular rate in this case likewise progressively decreased, as it has in one or two other cases, resulting finally in a fairly high grade bradycardia This rapid early irregularity is usually followed by a rapid regular rhythm (auricular flutter), the "*Transition* rhythm" of Eyster and Fahr The rate estimations in three cases, given in Table 5, show the initial ventricular, the transition rhythm and the final sinus rhythm rates

TABLE 5—RATE ESTIMATIONS IN THREE CASES

Initial Ventricular Rate	Rate of Transitory Rhythm	Sinus Rhythm Rate
111	130	60
80	133	73
94	107	70

In regard to the effect on the vagus, White believed that quinidin has a paralyzing effect, while Jackson, Friedlander and Lawrence believe that the vagus endings are not paralyzed and that the inhibitory action, if anything, is increased Lewis, Drury, Iliescu and Wedd[19] conclude that it causes a partial, rarely complete paralysis of the vagus From our experiences we have no evidence as to the vagus effect unless the acceleration of ventricular action under quinidin can be offered as evidence of such action Eyster and Fahr found the venous pressure increased as a result of the drug Cohn[20] found a fall in arterial blood pressure, and the Cincinnati workers describe a general fall in the systemic blood pressure Dilatation of pulmonary arterioles and capillaries resulting in a fall in pulmonary pressure has been described, as well as dilatation of peripheral vessels from direct action on the capillaries

CHANGES IN P-R INTERVAL, QRS COMPLEX, T WAVE, HEART BLOCK

Levy found the P-R interval lengthened in one patient White found it slightly lengthened Wolferth believes that it increases above the normal with the restoration of sinus rhythm, but that this is not necessarily due to quinidin We have found no constant effect, but have one strikingly prolonged interval in an unfavorable case Several observers have noted a lengthening in the QRS complex, with the production of transient intraventricular block and changes in R and S Several of our cases have shown slight prolongation and notchings in the initial complexes, and in two cases inversion of T The latter is in accord with several observers in this country White records one case of complete heart block Lewis concludes that it depresses auriculoventricular conduction as part of the uniform influence of the drug on the rate of conduction in all three tissues—auricle, ventricle and junctional tissues

cases the conditions tending to produce auricular fibrillation are still present even after a normal rhythm is restored, subsequent administrations of the drug are necessary to avoid recurrence If stoppage of the drug is followed in a short time by a relapse, we start a second series of quinidin administration, continuing it practically indefinitely, meanwhile making every possible attempt to diagnose and treat the probable underlying causative disease It is remarkable how long and uneventfully patients can take small amounts of quinidin Several of our patients are continuing now in their second and third month taking one or two capsules (0 2 gm) a day without apparent harm

DIGITALIS

The rôle of digitalis has been and continues to be a much discussed one Pardee believes there is no effect either way from its administration Wolferth had an interesting experience in which the administration of digitalis was effective in restoring a sinus rhythm temporarily, later, quinidin was not successful Robert Levy [16] believes that digitalis is not essential to successful treatment Fred Smith feels that it is contraindicated, as both digitalis and quinidin may produce heart block White concludes that digitalized cases are more likely to respond, but that it is better not to give the two together Lewis believes that there is little difference in the auricular response, although possibly the undigitalized cases may be a shade more likely to respond than the digitalized, but he strongly feels that digitalis effects are desirable, especially in the rapid type of fibrillation, and shows graphically in one and the same patient the relative slowing of the ventricular rate in the digitalized cases We have had three interesting experiences To one patient, in whom, in spite of evident decompensation (cyanosis and orthopnea) digitalis was certainly indicated, we gave quinidin first without digitalis, and a prompt restoration of sinus rhythm occurred, with a simultaneous disappearance of signs of heart failure The second case, reported last year, showed without digitalis and with small amounts of quinidin a clearing up of early heart failure and disappearance of evidences of right heart embarrassment (right preponderance) In the third case, an exophthalmic goiter patient with an extremely rapid type of fibrillation, we had great difficulty in maintaining, without digitalis, a normal rhythm for more than a few hours until a time when he was completely digitalized, after which the same or even smaller amounts of quinidin were successful in holding his heart regular for three weeks As a result of these experiences, our practice at present is to give quinidin at once in a properly selected case without preliminary digitalization, in spite of a moderately rapid heart and signs of early or moderately advanced heart failure If, on securing a normal rhythm, the ventricular rate remains over 100, or if the signs of heart failure have not disappeared entirely, or if the restoration of a regular pulse is of short duration with frequent and early tendencies to relapse, we then digitalize the patient in the usual way

SUBJECTIVE SYMPTOMS, CLINICAL VALUE, EFFECTS ON COMPENSATION AND DECOMPENSATION

The symptoms mentioned most frequently in the literature as due to the administration of quinidin are palpitation, weakness and dizziness, dyspnea, oppression and tachycardia A few have noticed epigastric distress, ringing in the ears, headache, nausea, hemoptysis and hot flashes Some of these complaints have been voiced by our patients, others have noticed no subjective effects of any sort

From the standpoint of the effect on subjective complaints, that is, the value of the treatment from the patient s standpoint, the literature contains such statements as "no striking change", "no more than ordinary rest and diet", "relief experienced in slow type of fibrillation", "relief from palpitation", "general improvement" Lewis makes the interesting observation that, although several of his patients showed no immediate improvement and experienced no immediate change with restoration of normal rhythm, they experienced later improvement in strength, in general well-being and in ability to carry on In our experience, the private cases have experienced decidedly more personal satisfaction from the change than the ward cases, not only patients with exophthalmic goiter but also those with acute fibrillation following infection, they are extremely grateful when the irregularity has been stopped Our easy-going, phlegmatic patients noticed little if any change, our nervous, apprehensive, frightened ones were intensely frightened during the attack and strikingly relieved when it was over, and insisted on having their capsules near them day and night One patient with goiter, whose attacks often come at night, puts his capsules at his bedside and helps himself when his attacks rouse him from his sleep

Several men have reported that quinidin caused decompensation in a previously well-compensated fibrillating heart, or at least, with the restoration of sinus rhythm by quinidin, decompensation occurred We have fortunately had no such experience

TOXIC EFFECTS, ACCIDENTS OCCURRING DURING QUINIDIN THERAPY (EMBOLISM), RESPIRATORY PARALYSIS, SKIN LESIONS

Wilson and Herrmann [17] group the accidents occurring under quinidin therapy under six headings (1) increased cardiac failure, (2) apparent respiratory paralysis, (3) embolism, (4) failure of the sinus node to resume function, (5) depressed intraventricular conduction, (6) increased ventricular rate Embolism is, of course, the most serious, has resulted in several sudden deaths, and has caused infarcts in the kidney, lung spleen and brain It has caused transitory paralyses

We have been fortunate up to the present time in having no embolic cases, at least none that we recognized We have had several scarlatiniform rashes, dizziness and ringing in the ears, spots before the eyes and sudden rise of temperature to 101 6 with severe headache, diarrhea and abdominal pain Such results as these are frequent findings throughout the literature The less serious findings are undoubtedly cause for immediate discontinuance of the drug We fully agree with Sir Thomas Lewis that any evidence of embolism is an absolute contraindication It is striking that several clinics report a much greater number of these accidents than others In this connection, it might be recalled that embolism is not an infrequent occurrence in fibrillation without quinidin, witness the reports of paralysis, infarcts, hemoptysis, etc, in the older literature

EFFECT ON AURICULAR AND VENTRICULAR RATE, VAGUS VENOUS, ARTERIAL AND PULMONARY PRESSURE, AND PERIPHERAL VESSELS

Acceleration of the ventricular rate (ventricular tachycardia) is a frequent experience in patients undergoing quinidin treatment Drury and Iliescu,[18] by using sternal leads, have shown clearly the progressive depression of auricular rate, falling sharply from a single dose and only very gradually resuming its original rate We have taken sternal leads in connection with the regular leads in a number of cases, and have estimated the auricular rate (Fig 3) Table 4 shows the typical result of such estimation, showing

TABLE 4—REGULAR AND STERNAL LEADS CASE 11

Date	Hour	Leads	Auricular Rate	Ventricular Rate	Rhythm
3/7/22	8 p m	Regular before quinidin	461 (approx)	171	Irreg (fibrillation)
3/8/22	8 a m	0 2 gm Q			
	10 a m	0 2 gm Q			
	11 a m	Sternal	408 (approx)	141	Irreg (fibrillation)
	12 noon	0 2 gm Q

	2 p m	0 2 gm Q			
	3 p m	Regular	260	130	Reg (flutter)
	4 p m	0 2 gm Q			
	5 30 p m	Regular	240	120	Reg (flutter)
	6 00 p m	0 2 gm Q			
3/9/22	8 00 a m	0 2 gm Q			
	9 45 a m	Regular	100	100	Normal (S R)
	4 30 p m	Regular	75	75	Normal (S R)

the gradual depression of an original auricular rate of 460 during fibrillation to 260 during flutter, and finally to 75 with the restoration of sinus rhythm In contrast to Lewis' findings, the ventricular rate in this case likewise progressively decreased, as it has in one or two other cases, resulting finally in a fairly high grade bradycardia This rapid early irregularity is usually followed by a rapid regular rhythm (auricular flutter), the "*Transition* rhythm" of Eyster and Fahr The rate estimations in three cases, given in Table 5, show the initial ventricular, the transition rhythm and the final sinus rhythm rates

TABLE 5—RATE ESTIMATIONS IN THREE CASES

Initial Ventricular Rate	Rate of Transitory Rhythm	Sinus Rhythm Rate
111	130	69
83	133	73
94	107	75

In regard to the effect on the vagus, White believed that quinidin has a paralyzing effect, while Jackson, Friedlander and Lawrence believe that the vagus endings are not paralyzed and that the inhibitory action, if anything, is increased Lewis, Drury, Iliescu and Wedd[19] conclude that it causes a partial, rarely complete paralysis of the vagus From our experiences we have no evidence as to the vagus effect unless the acceleration of ventricular action under quinidin can be offered as evidence of such action Eyster and Fahr found the venous pressure increased as a result of the drug Cohn[20] found a fall in arterial blood pressure, and the Cincinnati workers describe a general fall in the systemic blood pressure Dilatation of pulmonary arterioles and capillaries resulting in a fall in pulmonary pressure has been described, as well as dilatation of peripheral vessels from direct action on the capillaries

CHANGES IN P-R INTERVAL, QRS COMPLEX, T WAVE, HEART BLOCK

Levy found the P-R interval lengthened in one patient White found it slightly lengthened Wolferth believes that it increases above the normal with the restoration of sinus rhythm, but that this is not necessarily due to quinidin We have found no constant effect, but have one strikingly prolonged interval in an unfavorable case Several observers have noted a lengthening in the QRS complex, with the production of transient intraventricular block and changes in R and S Several of our cases have shown slight prolongation and notchings in the initial complexes, and in two cases inversion of T The latter is in accord with several observers in this country White records one case of complete heart block Lewis concludes that it depresses auriculoventricular conduction as part of the uniform influence of the drug on the rate of conduction in all three tissues—auricle, ventricle and junctional tissues

SUMMARY

It is difficult to reach final conclusions regarding the exact role of quinidin in auricular fibrillation This

18 Drury A N and Iliescu C C Brit M J 2 511 (Oct 1) 1921

19 Lewis Thomas Drury A N Iliescu C C and Wedd A M *Heart* 9 55 (Dec 14) 1921

difficulty arises from several sources, because (1) of our comparatively short acquaintance with the phenomenon, (2) our lack of knowledge concerning the exact mechanism and underlying cause of fibrillation itself, and (3) the new experiences and findings from each fresh case undergoing treatment

Stating first our general impression, in spite of our relatively few cases of permanently established sinus rhythm (27 per cent), we feel that quinidin is establishing a permanent place for itself in cardiac therapy and that no case of auricular fibrillation should be treated at the present time without at least thoughtful consideration of its therapeutic possibilities Starting, then, from this general favorable impression, which are the cases that are most likely to respond, either permanently or temporarily? Judging by our experience up to the present time, we feel that patients with acute fibrillation or recurrent paroxysmal fibrillation are those most likely to react favorably and promptly to

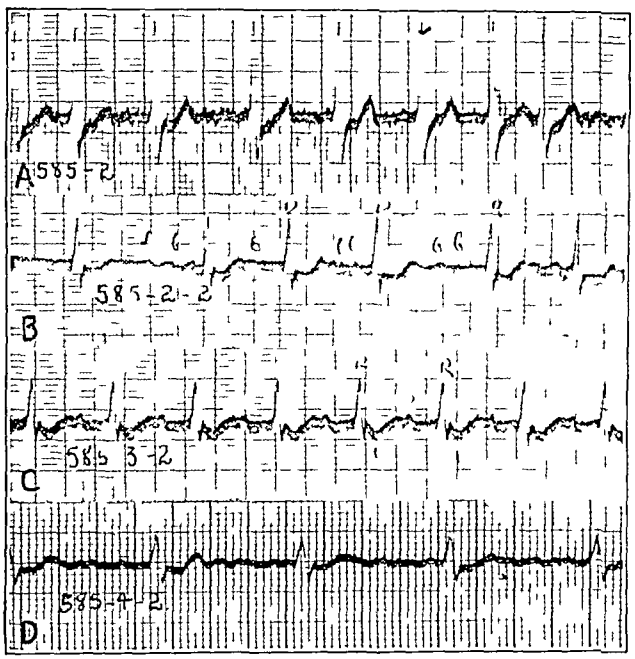

Fig 2 (Case 15 woman aged 50) —Chronic auricular fibrillation mitral stenosis regurgitation advanced recurring heart failure Quinidin response brief early relapse to fibrillation prolonged P R example of contraindication Following 0 2 gm temperature 101 6 F Died suddenly one week later *A* Aug 19 1921 rate 94 no quinidin *B* August 23 rate 75 no quinidin *C* September 2 rate 107 2 6 gm quinidin *D* Feb 8 1922 rate 79 total quinidin 7 4 gm

quinidin While in these patients fibrillation often ceases spontaneously, administration of the drug controls the paroxysms more promptly and without danger The duration of the response is more likely to be permanent in acute self-limited illnesses (acute respiratory infections, pneumonia) than in cases of hyperthyroidism, generalized arteriosclerosis, etc

The next most favorable type of case is the patient with fibrillation of relatively short duration without signs of heart failure or evidence of embolism, in whom the administration, so far as we know, is unattended with serious consequences

The third group, in which the outlook for response is probably as good as the second, but in which the possibilities of danger are somewhat greater, comprises those patients with signs and symptoms suggestive of beginning or early heart failure (*cyanosis, dyspnea* palpitation and tachycardia), but without the signs of advanced heart failure (engorged tender liver, pulsating veins of the neck, dropsy, etc) In these the response is often remarkable These cases suggest that the cyanosis, dyspnea and palpitation are due to the mechanical effects of the rapidly beating ventricle, and not to ventricular muscle failure

We come now to the fourth group, the unfavorable cases or those in which quinidin is absolutely contraindicated They may be listed briefly as those patients suffering with moderately advanced or advanced heart failure, signs or history of embolism, acute or subacute endocarditis, auriculoventricular or intraventricular block, angina pectoris, coronary disease, idiosyncrasies for quinin and its derivatives, or prolonged chronic fibrillation In these patients, the results of quinidinization are not sufficiently striking to justify the potential risk involved

The drug should not be given without a careful history and complete examination of the patient If possible, a preliminary electrocardiogram should be made, for without it there must always exist some uncertainty as to the exact type of irregularity or the presence of additional irregularities (extrasystoles), the relative balance of the right and left heart, and the integrity of the ventricular muscle (disturbance in ventricular conduction) The patient should be put at complete rest in bed, given a preliminary idiosyncrasy test of 0 2 gm, and then starting the following day the same amount every two hours with continuous observation and control, including the electrocardiogram if possible Digitalis should be given later if the ventricular rate remains high, if heart failure persists, or if frequent relapses to fibrillation occur

CONCLUSIONS

1 Quinidin sulphate has been administered to eighteen patients suffering with auricular fibrillation In eleven (61 per cent) a normal cardiac mechanism has been established, which, in five (27 per cent), has persisted three months or more One patient has maintained a sinus rhythm uninterruptedly for eleven months

2 Cases of acute fibrillation or recurrent paroxysmal fibrillation are most amenable to quinidin treatment In these patients the duration and frequency of the paroxysm can be promptly controlled without undue risk

3 The following is offered tentatively as a means of selecting cases of auricular fibrillation in the order of their decreasing suitability for quinidin treatment (*a*) patients with acute fibrillation or recurrent paroxysmal fibrillation, (*b*) patients with fibrillation of short duration without history or findings of heart failure or embolism, (*c*) patients with signs and symptoms of early or apparent heart failure, but without evidence of advanced heart failure

4 In patients with moderately advanced or advanced heart failure, and history or findings of embolism, endocarditis, heart block, angina pectoris, coronary disease, quinin idiosyncrasy or prolonged chronic fibrillation, quinidin is contraindicated

5 Equally good results are obtained with small amounts of quinidin (0 2 gm) given frequently (every two hours), to be continued in most cases once or twice daily after restoration of sinus rhythm

6 Quinidin may usually be given at once without preliminary digitalization If, after restoration of

normal rhythm, the ventricular rate remains high, signs of heart failure continue, or frequent relapses to fibrillation occur, digitalis should be subsequently administered

ABSTRACT OF DISCUSSION

DR FRED M SMITH, Chicago Every one has been impressed by the remarkable action of quinidin in auricular fibrillation The beneficial effects of this drug in this disorder are not, however, as promising as it was thought they might be It is apparently generally agreed that quinidin will ultimately be established as a valuable drug in the treatment of certain cardiac disorders So far the results seem to be much better in instances of auricular fibrillation of short duration in which the heart is well compensated A few fatalities have been attributed to the administration of quinidin In most instances cardiac failure or emboli have been responsible for the unexpected results Lewis recommends that patients be well digitalized prior to the administration of quinidin His reason for this is to ward off the possibility of embolic accidents At present, it would thus seem that the dangers incident to this method of treatment would not permit its being recommended to the general practice Observations would seem to indicate that quinidin may, perhaps, be of value in the treatment of permature contractions It is commonly known that the premature beat may be a very disturbing condition to the patient and often not influenced by the measures that have been employed in the past In several instances, we have obtained very satisfactory results with quinidin in persons who did not respond to other forms of medication I well recall one patient who came to the clinic because of an irregular action of the heart that had occurred daily for an interval of more than five months His general condition was very poor He was unable to continue his work He had lost 20 pounds (9 kg) in weight, was unable to sleep and had a poor appetite He was instructed to take 3 grams of quinidin three times a day The irregularity was eliminated He began to sleep regained his appetite and in one week gained 10 pounds (4 5 kg) in weight At present his weight has increased more than 25 pounds (11 3 kg), he is back at his former work and feels better than he has in months

DR JOHN WYCKOFF New York Dr Hamburger said that quinidin was not indicated in cases of severe, long standing decompensation I agree, but I think there are two reasons why it is contraindicated first, as Dr Hamburger has said because in this type of case quinidin is most dangerous, although it is interesting to note that in the twenty-four cases of auricular fibrillation which I have observed the only death occurred in a patient who had no symptoms of heart failure at the time he received quinidin, and, second, because the clinical improvement after quinidin is very much less than that which we obtain after digitalization It has been our practice to place patients with auricular fibrillation with heart failure into two groups In one group we gave digitalis first and after we had obtained full digitalis effect, we gave quinidin In the other groups we gave quinidin first followed later by digitalis Patients were given a preliminary rest period of seven days with limited fluid intake so that these factors could be eliminated as a cause of improvement They were ordered rest for a week, and then given quinidin Though some of these patients resumed sinus rhythm, none of them showed further clinical improvement The other group were given quinidin first Those who returned to normal rhythm usually showed some slight clinical improvement After seven days' continued rest with the normal rhythm, these patients were digitalized, and every one of them showed marked further improvement For example one patient with a ventricular rate of 160, with signs of advanced heart failure after receiving quinidin, resumed a normal rhythm with a ventricular rate of 90 The only clinical improvement was that palpitation disappeared The patient was given a further rest for one week During this time, dyspnea and orthopnea persisted and there was no loss of weight He was then digitalized with an immediate clearing up of his symptoms He passed 4 liters of urine in the first twenty-four hours and lost 15 (6 8 kg) pounds weight in the first forty-eight hours This, I believe shows that quinidin cannot take the place of digitalis in this type of case

DR ARTHUR E STRAUSS, St Louis Quinidin has certainly come to be experimented with, even if it has not come to stay The use of quinidin is still in an experimental stage As with all drugs it must undergo a period of study and our final analysis must depend on this study Dr Hamburger has emphasized that quinidin apparently is most effective in the cases of transitory auricular fibrillation In that connection I think it important to say that we are not certain that all so-called chronic fibrillations do not begin first as periods of transient fibrillation Certainly, if one takes careful histories, one will often see cases develop as transient fibrillation, and it is not infrequent to see such cases develop later into the chronic forms If quinidin is valuable in the temporary fibrillation it is valuable in the chronic fibrillations at the onset Dr Hamburger has stated that it is often

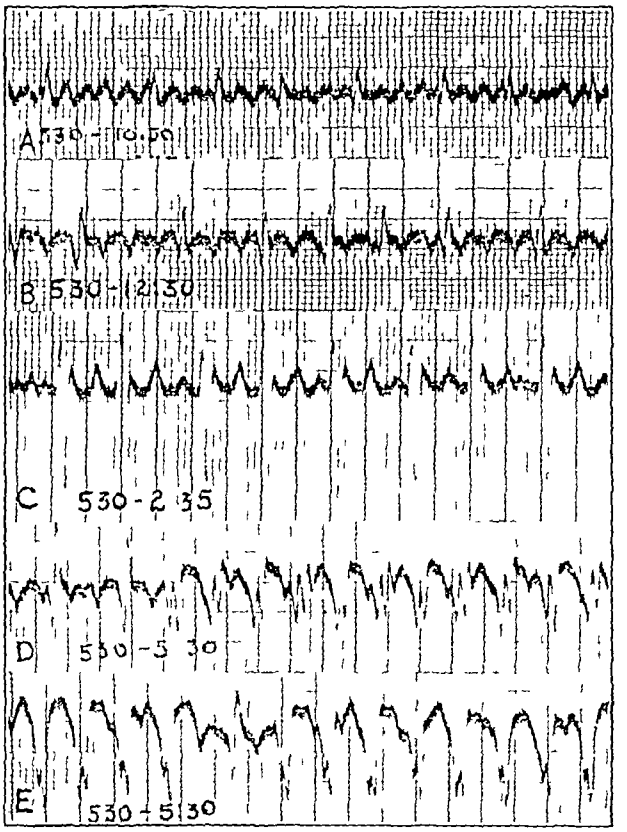

Fig 3 (Case 5) —Sternal lead curves showing effect of quinidin on auricular and ventricular rate Nov 28 1922 *A* 10 30 a m no quinidin auricular rate 424, ventricular rate 124 *B* 12 30 p m after 0 1 gm auricular rate 382 ventricular rate 150 *C* 2 35 p m after 0 2 gm auricular rate 363, ventricular rate 124 *D* 5 30 p m. after 4 gm auricular rate 375 ventricular rate 230

necessary to continue the administration of quinidin We are not yet certain of the effects of the long-continued use of quinidin We have seen quinin used in malaria for long periods of time and in the majority of cases we have noted no harmful effects However, in a number of my cases of fibrillation in which quinidin has been used for long periods the patients have complained of weakness when they had no symptoms of idiosyncrasy to quinidin Therefore, there is some doubt as to how long quinidin can be continued It must further be emphasized that there are some dangers incident to the administration of quinidin Therefore it must be used only after due consideration and with the idea that it should be as carefully controlled as are all experiments One final word as to the reason we should not use quinidin in the decompensated hearts We know that digitalis in the decompensation of fibrillation is almost invariably beneficial We know that quinidin is beneficial in restoring normal rhythm

in no more than 60 per cent of cases on the average That alone is sufficient reason for using digitalis in the decompensated fibrillators, rather than quinidin

DR ALEXANDER LAMBERT, New York I have tried quinidin in thirty cases In one patient, the fibrillation stopped and the rate fell to normal In all the others, with careful electrocardiographic control, there was no effect

DR L F BISHOP, New York Dr Hamburger has probably made the best observations and written the best literature on quinidin So that, in discussing his paper, I do not wish to add to the experimental side of it, but rather to give my own impressions founded on a rather unusual group of patients For a number of years, I have been using the electrocardiograph in private practice, and I have instructed my patients to come to the office when they have palpitation and have a picture taken of the heart beat Thus I have accumulated a number of examples of temporary fibrillation which did not recur again for a long time or did not recur at all It seems to me that a very important element in appraising the value of quinidin is a knowledge of the natural history of fibrillation I believe that nearly every example of fibrillation, except in the very advanced broken-down heart, begin in this way The vast number of fibrillators commence by short attacks which become more frequent and last longer It is almost a joke on medical science that the best example of therapeutic effect should be disturbed by the introduction of a new treatment There is no treatment in all medicine as brilliant as the treatment of fibrillation of the auricle with digitalis, and I would say as a matter of experience that the patients do not feel any better when they are treated by quinidin than when they are treated by digitalis In other words, the chronic fibrillator carries fibrillation comfortably if he takes enough digitalis or if he develops heart block which balances the fibrillation I have seen persons who have continued very well with fibrillation for fifteen years or more There is no doubt that there often exist clots in the paralyzed auricle in fibrillation and it is certainly dangerous to restore the contraction of that auricle if it is going to throw out an embolus which may kill the patient I do not believe that quinidin is a valuable general heart tonic and I believe that men in general practice will do well if for the present they leave the use of quinidin to men who are experimenting with it in hospitals I think it is unwise to use it in ambulatory patients in private practice

DR WALTER W HAMBURGER, Chicago I agree with Dr Bishop in the main I think his warning in the advanced cases should be emphasized The real danger is, of course embolism If there is any sign or history of embolism quinidin should not be given One of my patients is a surgeon who has had paroxysmal attacks of fibrillation for fifteen years He gets attacks once a year or so, sometimes while operating, once while swimming and the last time while working in his garden The attack last year lasted about a week and was associated with severe anginal pains He was worried about it and was quite ill After a week's rest in bed, the fibrillation stopped of its own accord and he has had no attack until a week ago I immediately gave him 3 grains (0 2 gm) of quinidin and another dose in two hours Within three hours this attack was over and he is confident the drug shortened the attack Likewise in the paroxysmal attacks of exophthalmic goiter, quinidin undoubtedly controls the attacks It should not be given to ambulatory patients, and it should not be given as a routine until we know much more about it than we do at the present time Embolism occurs in fibrillation without quinidin and sometimes without the establishment of a normal rhythm

Purpose of Operation for Epilepsy—In operating on epileptics, and in choosing cases for operation, we should like to have a clear idea of the purpose of the operation, based on some reasonable conception of that relationship The surgeon who merely removes a disk of bone from the cranium of an epileptic patient places himself on a level with the practitioner of the stone age the marks of whose handiwork on the skulls, probably of the epileptic or the insane, are to be seen in museums of ethnology —Percy Sargent, *Brain* **44** 314 1921

THE CAUSE AND RELIEF OF ACUTE INTESTINAL OBSTRUCTION*

CHARLES H MAYO, M D
ROCHESTER, MINN

Ileus is one of the most serious conditions that confront the medical attendant, since if it is not relieved death is inevitable In order to lower the death rate in such conditions, much depends on early diagnosis, judgment and promptness of action Relief is by no means possible in all cases, for instance, there is necessarily a high mortality in cases of mesenteric embolism and thrombosis Therefore, the discussion of the subject of acute intestinal obstruction, from time to time, is of value, not so much for the older practitioners as for those who have more recently entered the profession, so that they may acquire knowledge without encountering the tragedies which fixed the memory of such conditions in the minds of those long in practice

Cases of acute intestinal obstruction may be regarded as falling naturally into four groups (1) apparent obstruction, really intestinal stasis, a reflex symptom occurring with slight abdominal distention, the pulse and temperature changes being such as are caused by the primary lesion, which is often renal, (2) the obvious hernia, (3) acute obstruction from an intra-abdominal lesion, and (4) postoperative obstruction

The obvious hernias, inguinal, femoral, umbilical and ventral, which formerly caused a considerable proportion of obstructions through strangulation, have now largely been taken from this group, as even laymen appreciate the safety of modern surgery over that of a few decades ago Hernia repaired at an elective period prevents the high percentage of strangulations formerly seen, when a reasonable fear of surgery led to prolonged taxis which often aided in the development of gangrene The wasted opportunity, added to the seriousness of preantiseptic surgery, gave a high mortality which resulted in making acceptable this vicious circle of delay Gangrene, or wet death of tissue, especially abdominal, and when sepsis is possible, furnishes toxins which are most difficult to counteract without the removal of the destroyed tissue or without adequate drainage

Obstructions within the abdomen are those which cause the greatest apprehension, as there are added difficulties of diagnosis, some of which have been overcome by fluoroscopic observation or roentgenograms revealing obstructions after the opaque material has been given by mouth or by rectum Volvulus from the twist of an extra long mesentery, usually of the sigmoid, produces not only obstruction but also the toxins of tissue death Various forms of internal hernia, beneath bands, through congenital or unnatural mesenteric openings or through the diaphragm, usually cause degrees of partial, chronic, rather than acute, obstruction, which, however, may suddenly supervene A second form of toxin concerning which much has been written is still under discussion It is observed in obstructions high in the jejunum, blocking the duodenum, and, although the exact cause of retention is not always known, the condition is recognized Such an obstruction around the duodenojejunal juncture, with paresis and dilatation of the duodenum may cause

* Read before the Section on Obstetrics Gynecology and Abdominal Surgery at the Seventy Third Annual Session of the American Medical Association S Louis May 1922

alkalosis with tetany, in which there is loss of the chlorids and a great general loss of calcium which chokes the renal tubules This is most serious and is attended by vomiting of green fluids having but little odor At first, the vomitus is usually watery and contains undigested food particles, and later bile, but the green vomitus probably originates largely in the upper duodenum In obstruction of the jejunum or ileum, the green vomitus may be noted the second day, followed later by regurgitant brown and darker colored fecal or foul smelling fluids The true toxin of pancreatic and duodenal ferments is most difficult to counteract, but relief is obtained or life is prolonged by removing the fluid at regular and frequent intervals with a stomach tube The mortality is high because efforts to relieve the obstruction surgically are made late The operation must drain the duodenum below by jejunostomy and a tube passed to the duodenum, or through the stomach, by gastrostomy and a tube through the pylorus, or by duodenojejunostomy

Obstruction of the stomach at the pylorus causes death from inanition, yet if fluids can be supplied subcutaneously, by rectal tube or nutritional jejunostomy tube, life can be prolonged for a considerable period Obstruction below this point becomes serious early because of the toxemia, although danger of this is less acute, the lower down the obstruction occurs, and if the obstruction is in the large bowel, several days may be added to the possible period of surgical relief over that if the obstruction is in the small intestine In the latter case, the later the operation, the higher the mortality for any given procedure After the first day each hour increases the danger of the condition The toxemia then from colonic obstruction is of less relative importance than perforation, peritonitis and inanition, if the stomach is kept empty by regular tubation

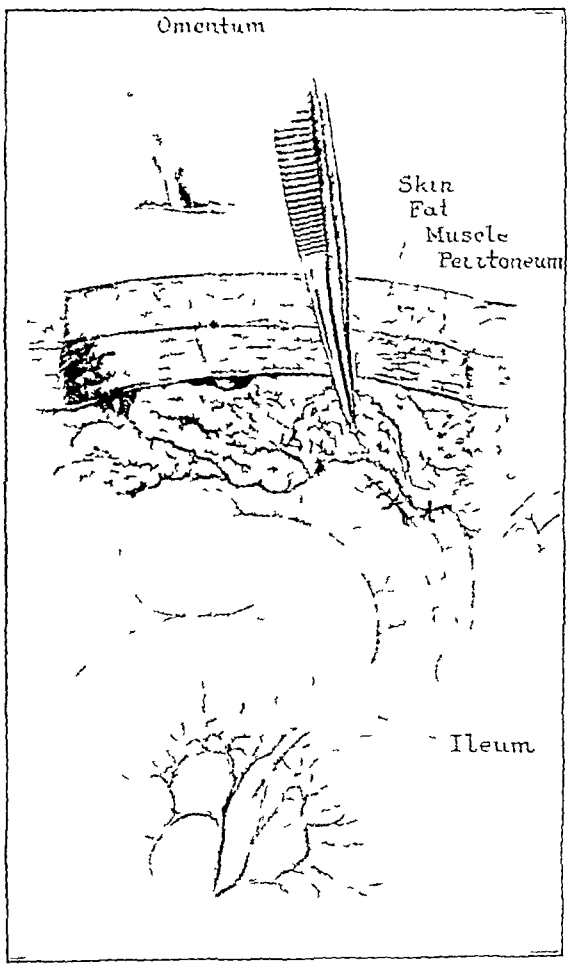

Fig 1—Ileostomy with a rubber tube which passes from the lumen of the intestine through the intestinal wall omentum and abdominal wall

Intussusception, with its sudden onset, cramps and pain, with blood and mucus, may often be located by a palpable tumor, especially in children under 1 year of age, among whom from one third to one half of such conditions are found In adults intussusception is often started by a tumor, benign or malignant, of the small intestine The papilloma or adenoma becomes grasped in peristaltic action, the bowel being drawn in behind as it moves forward within its lumen, usually thus producing a tumor of palpable size An inverted Meckel's diverticulum may act in the same way, or a stiff infected area on the cecum around the base of the appendix may become the invaginating head Operations are rarely performed early enough that the intussusception may be milked back, and it is usually necessary to perform some degree of resection of the bowel and intestinal anastomosis Gross tuberculosis in the small or large bowel occasionally causes complete obstruction following a series of chronic, recurring incomplete obstructions In the large bowel, malignancy accounts for the great majority of these conditions, the obstruction is rarely due to the pressure of tumors except those that are usually obvious or palpable, and even in cancerous obstruction, in most instances, there are recurring attacks of incomplete obstruction which are characterized by the passage of blood streaked mucus before it becomes complete Sudden, severe pain with shock usually signifies the completion of obstruction, especially if due to a twist or to mesenteric thrombi or emboli, the latter, as a rule, being secondary to endocarditis

In hernia, gangrene, volvulus or vascular obstruction, there is usually a rapid increase in the leukocyte count. A large gallstone may ulcerate through the gallbladder and duodenal walls, and, after passing through the upper intestine, cause a block in the lower ileum While a previous history of probable gallstone disease may be elicited after operation, indication for exploration in acute ileus will continue, and the procedure will disclose many causes of obstruction that are relievable and some that are unrelievable Promptness of action is essential in making an exact diagnosis of the cause

In many years of active surgical work I have not seen death occur as the result of an unnecessary exploration I have seen many patients saved and some die of disease, but many died solely because exploration was undertaken too late

TREATMENT

Most patients are moribund or nearly so at the time procedures are undertaken for the relief of obstruction of the large bowel If the obstruction is the essential feature, I should warn against any endeavor to make the operation other than a life-saving drainage procedure as colostomy, enterostomy or appendicostomy The last is of little value and becomes absolutely dangerous, unless the appendix is large and patulous and will admit the passage of a large catheter without tension, otherwise cecostomy is indicated

Exploration must be made to determine whether or not the obstruction is malignant or is due to congenital diverticulitis Sometimes this is impossible because of adhesions and infections Acquired diverticulitis is rarely so small in area or confined to so few or to such small pockets that the diverticula will not show in the barium shadow True congenital diverticula are more rare, resemble malignancy and may even develop malignancy If the condition is malignant, examination of the liver, glands and intestines should be made in order to ascertain whether future operation is advisable and just what procedure should be carried out

An endeavor to make the primary operation complete, with removal of the growth, probably doubles the danger over that of a two-stage procedure

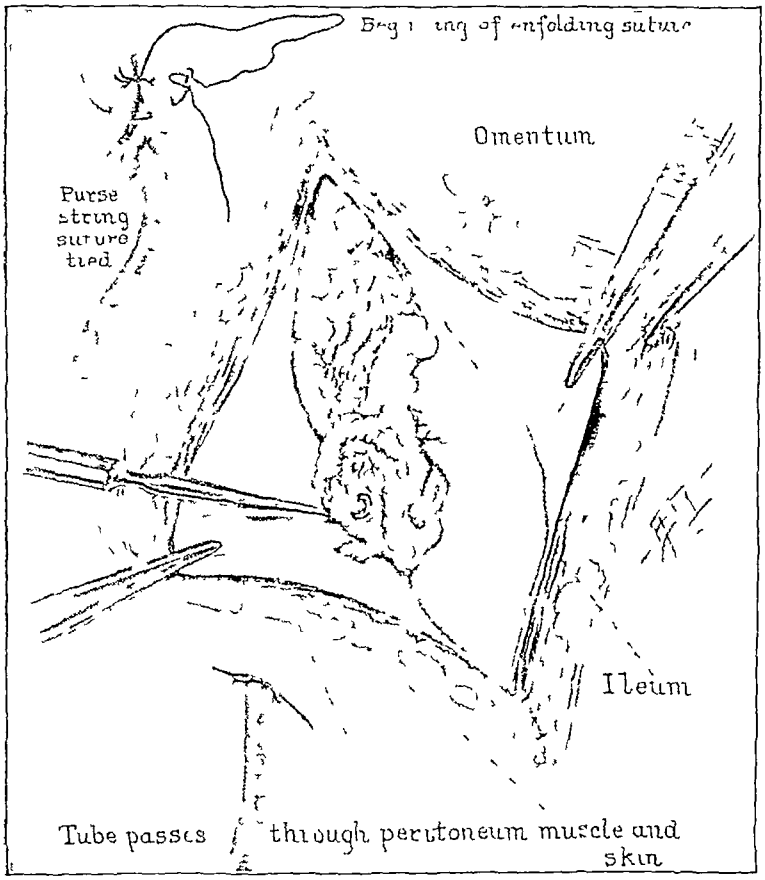

Fig 2 —Abdominal wound showing position of rubber tube in relation to the ileum in its course as it passes through the omentum and abdominal wall

Obstruction following operative procedures such as gastro-enterostomy, or the removal of pelvic infections is a real tragedy While we blame the patient and the medical attendant for delay in calling council in the obscure cases of obstruction, the same delay occurs in hospitals in postoperative cases, and there is a lack of promptness of action, because of the hope that the obstruction is partial and will "clear up tomorrow"

In diagnosing localized peritonitis with the stethoscope, one may hear some tinkling movement of fluids and gases which is not noted in general peritonitis with attendant obstruction from paresis General peritonitis is accompanied by an even distention as compared with the irregular distention accompanying peristaltic activity of the stomach and small intestines, which is more manifest the lower the obstruction

When complete obstruction supervenes, several small, loose, natural, but painful, movements may occur, and there is violent peristaltic action above in the endeavor first to overcome the obstruction, and failing in this to reverse peristalsis and empty the bowel contents into the stomach Usually vomiting and rarely dilatation occurs The latter doubles the danger if unrecognized Therefore, the use of the stomach tube is the most valuable test we have for the purpose of determining the condition of the stomach and the amount of intestinal contents therein, and it must be used repeatedly to prevent dilatation I should prefer to see a stomach tube rather than a stethoscope hanging around the neck of my surgical intern

If local obstruction occurs following gastro-enterostomy, turning the patient on his face or on the left side sometimes aids in the passage of gastric contents into the intestine, probably because the opening is on that side, or possibly because of a change in circulation of the superior mesenteric vessels In postoperative obstruction, if the abdomen is opened within twenty-four or thirty-six hours after the beginning of symptoms, the filmy adhesions causing kinks or twists can be separated with little difficulty, and with immediate benefit Later, but little exploration is advisable for the purpose of ascertaining the cause or exact location of the obstruction, and enterostomy, as advised by Nelaton, should be made for relief If the obstruction has followed pelvic operation, an ileostomy may afford marked relief, a high obstruction demands jejunostomy for drainage or for nutritional purposes, and if the obstruction follows a gastro-enterostomy, the passage of a catheter into the stomach and down the jejunum through the gastro-enterostomy will accomplish the same results without narrowing the lumen of the jejunum In the presence of tetany, the tube must traverse the duodenum, being passed through the pylorus, and the patient saturated with lime

Early operation may be performed by reopening the abdominal incision Operation for obstruction after five days is best performed through a separate incision (Figs 1 and 2), as the cause of obstruction may be infection in the primary wound, with attachment and kink of the bowel at the infected point, and reopening the incision may spread the infection within the abdomen This may be prevented by working through a new incision The enterostomy tube for drainage or nutrition should also be passed through the omentum, and if infection was the cause of the trouble, the tube should be brought through a separate perforation of the abdominal wall at the point of election, permitting a better closure of the working incision This layer of omentum serves the same purpose as does the cellulose layer in the outer wall of battleships, closing the opening and preventing leakage after removal of the tube It also gives greater freedom than a direct adhesion of the intestine to the abdominal wall permits Such operations should be performed as far as possible under local anesthesia, or, in exceptional cases, under combined local and general anesthesia

In operations for relief of obstruction, it is often advantageous to be able to distinguish the proximal from the distal end of a loop of bowel Monk has suggested that the bowel be held in line with the spine, the thumb and finger enclosing the intestine If they are slipped down the mesentery, and if they pass directly to the mesenteric attachment without being reversed, the upper end is known to be proximal In order to distinguish the part of intestine to which an individual loop probably belongs without handling a great part of it, one should remember that the jejunum is much thicker and has a larger lumen than the lower ileum, also, the upper, thicker bowel has a thinner mesentery with translucent spaces, and there is much fat in the mesentery of the ileum which becomes thicker nearer its termination

ABSTRACT OF DISCUSSION

DR GEORGE W CRILE, Cleveland Dr Mayo has covered the subject, but I wish to emphasize three points which are most important 1 Intestinal obstruction demands immediate action, and yet the most careful and gentle action compatible with the relief of the obstruction It is essential not to do too much 2 It is extremely important in these cases to build up the water equilibrium of the patient who has been vomiting and has not been absorbing water Large amounts of water, even 7,000 c c, subcutaneously are indicated the first twenty-four hours 3 In order that the patient may have the proper oxidation within the tissues of the body, it is important, unless the circulation is good to give a blood transfusion, and to give it in advance of the indication of failure of the patient's organism If necessary morphin should be prescribed I am not afraid of giving large doses of morphin after the obstruction is relieved

DR C H MAYO, Rochester, Minn Twenty-five or thirty years ago appendicitis was discussed at every meeting of the American Medical Association Ochsner, Deaver, McBurney Murphy and others did a great deal to show that operation for appendicitis is safe in the first twenty-four hours, and that the danger is in the second, third and fourth days Ochsner's method of treating appendicitis seen too late for a safe early operation and too early for a safe late operation saved many hundreds of lives It appears to me that the mortality from appendicitis is greater today than it was twelve years ago when we stopped discussing the subject The important point to teach the younger men in the profession is that no time should be lost in examining such patients and in operating while it is safe to do so, instead of waiting for thirty-six or forty-eight hours Appendicitis is easily handled if it is attended to early A patient will never be lost because of a necessary exploration and many may be saved

Excessive Accident Fatalities in United States—The statistical bulletin of the Metropolitan Life Insurance Company announces that the number of deaths from accidents in the United States is twice as high in proportion to the population as that prevailing in England and Wales In the year 1920, which was characterized by lower accident rates than any year in the decade, there were 30,000 more deaths than would have been reported if the death rates of England and Wales had prevailed For the entire country, this means an excess of nearly 37,000 deaths The subjoined table presents the death rates per hundred thousand from principal external causes of death, 1920, in the United States registration area and in England and Wales

External Cause of Death	United States Registration Area	England and Wales
Total external causes	88 7	46 7
Accident and unspecified violence	71 4	36 9
Burns (conflagration excepted)	7 6	4 7
Drowning	5 7	5 0
Traumatism by firearms	2 6	3
Traumatism by fall	11 8	7 7
Traumatism by other crushing accident	21 6	10 2
Suicides	10 2	9 1
Homicides	7 1	8

PRIMARY CHANGES IN EYES OF RATS WHICH RESULT FROM DEFICIENCY OF FAT-SOLUBLE A IN DIET*

SHINNOSUKE MORI, M D
Chief of the Ophthalmological Clinic South Manchuria Railway Company Hospital
DAIREN, MANCHURIA

Of recent years, several investigators have described the eye disease which occurs in rats as the result of diets deficient in fat-soluble A Various names have

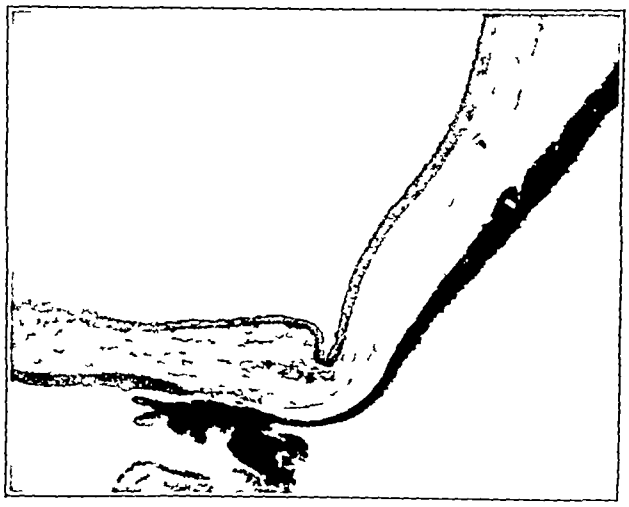

Fig 1 —Section through the normal eye in the region of the limbus

been given to this condition McCollum and Simmonds [1] termed it xerophthalmia They chose this name after careful study of the development, symptoms and treat-

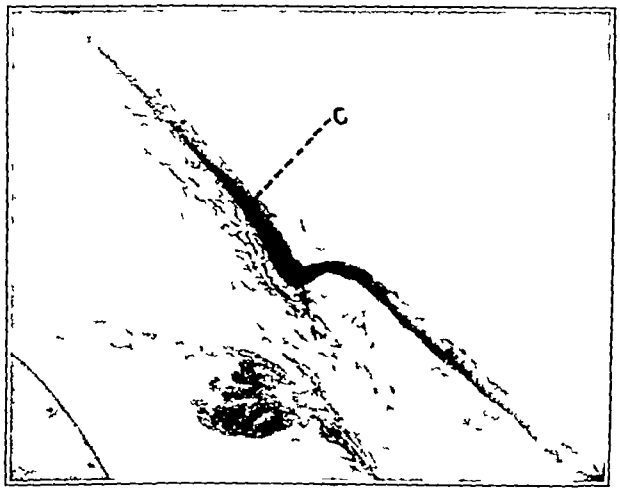

Fig 2 —Section through cornea and conjunctiva to show the beginning xerosis corneae and conjunctivae and the cornification (c) and thickening of the epithelium The substantia propria is thickened and infiltrated

ment of xerophthalmia as it occurs in rats and man Osborne and Mendel [2] preferred to use the more general term ophthalmia Goldschmidt [3] studied the pathology of the disease as it occurred among young

3 Goldschmidt M Arch f Ophth 90 545 1915

rats on Hopkins' diet His studies convinced him of the identity of the lesion with keratomalacia in man, and he proposed giving this name to the disease in the rat Stephenson and Clark [4] also preferred this term to xerophthalmia, for the pathologic condition in the eyes of rats seemed to them to resemble keratomalacia more closely than xerophthalmia The reported incidence of the disease among animals in different laboratories on deficient diets varies a great deal Stephenson and Clark produced the disease in 28 per cent of forty-six rats Osborne and Mendel observed the ophthalmia in forty-nine out of 136 animals Walker [5] found five cases in his first group of sixty-four animals In his second group of thirty-eight rats, six developed sore eyes Emmett,[6] on the other hand has stated that out of his 122 rats 120, or 98 3 per cent, sooner or later showed positive signs of xerophthalmia The incidence of the disease in any group of rats will depend on whether the diet is entirely or only partially deficient in fat-soluble A, and on the age of the animals

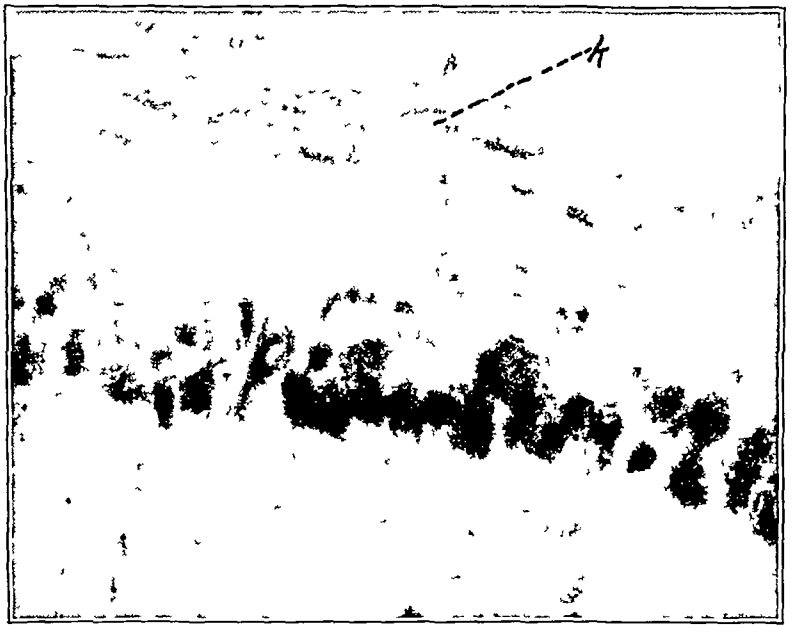

Fig 3 —Conjunctival epithelium showing keratohyaline (*k*) granules in the cells × 1 000

The pathologic changes in the eyes of experimental animals which were reported by Goldschmidt, Stephenson and Clark, Wason, and Walker, were for the most part those which result from inflammation and destruction or necrosis of the cornea No one has as yet described any specific preliminary alteration which is characteristic of this condition Stephenson and Clark [4] state that "the only criterion we possess for determining the preliminary change caused by the deficient diet is the appearance of the secondary symptoms caused by bacterial invasion," and they failed to demonstrate with certainty any histologic change in the cornea which preceded bacterial infection Wason [7] concluded that "no fundamental data concerning the etiology of ophthalmia in rats on deficient diet or the cause of the cornea localization have been derived from these anatomic studies"

The knowledge which we possess of ophthalmologic pathology, especially of the pathology of xerophthalmia and keratomalacia, would lead one to suspect that, if specific preliminary changes occur in the tissues of the eye before invasion by bacteria takes place, they will be found in the epithelium of both the cornea and the conjunctiva Therefore, if the disease in rats is to be identified with xerophthalmia or keratomalacia as they occur in man, the conjunctiva as well as the cornea must be the object of careful comparative study Such a comparison between the lesion of xerophthalmia in man and the eye disease produced in the rat by diets deficient in fat-soluble A was the object of my investigation The purpose of this paper is to report the early changes in the corneal and conjunctival epithelium which characterize the disease in the rat

Preparations were made from (*a*) the eyes of rats on a normal diet, (*b*) sore eyes without demonstrable affection of the cornea from rats on deficient diets, (*c*) eyes from animals showing clouded corneas on one or both sides, and (*d*) eyes with corneal ulcerations in several stages of development The eyes were fixed in 4 per cent solution of formaldehyd and embedded in celloidin, and stained with hematoxylin-eosin or with iron hematoxylin

The epithelium of the normal conjunctiva bulbi and the cornea consists of a superficial layer of flattened squamous epithelium, a deeper layer of polygonal cells, and beneath these a basal layer of columnar cells (Fig 1) Under normal conditions, the cells in the superficial layer retain their nuclei They are kept constantly moist by secretions The eyes of rats which have been fed on a diet deficient in fat-soluble A show two distinct and characteristic changes at the onset of the disease One of these is the cornification of the outer layer of epithelial cells of the conjunctiva bulbi, and the other the formation of granules of keratohyalin in the cytoplasm of the second layer of these cells The same cornification is also found in the corneal epithelium, but keratohyalin is not formed in the cornea except at the limbus In the process of cornification, the cells of the

conjunctival epithelium become flattened and loosened from the layer beneath They lose their nuclei and stain heavily with eosin At the same time, very fine granules appear, surrounding the nucleus in the cytoplasm of the second layer of cells These granules are deeply stained by hematoxylin, and by the Gram-Weigert stain, and are called "keratohyalin" (Figs 2 and 3) These two changes were shown by Leber[8] to be caused by dryness of the conjunctiva, and they are the characteristic changes of the xerosis conjunctivae of human beings Besides this cornification and the formation of keratohyalin, the epithelium of the conjunctiva is always somewhat thickened As the disease advances, cornification and keratohyalinization spread from the region of the limbus, where they first appear, throughout the conjunctiva bulbi to the fornix, and the conjunctiva palpebrae As was stated above, the epithelium of the cornea also becomes cornified The superficial cells near the limbus first become horny (keratinized), and their attachment to the thickened epithelium beneath which is often infiltrated by pus cells, becomes loosened Keratohyalin formation is usually absent from the corneal epithelium except

Fig 5—Section through the cornea showing epithelial necrosis followed by infiltration in the substantia propria and anterior chamber (*a*)

where that tissue joins the conjunctiva limbi The substantia propria shows a slight cell infiltration as a reaction to the epithelial change

In later stages of the disease, either one of two alterations may take place in the corneal epithelium The one consists of the destruction of Bowman's membrane and the abnormal thickening of the layers of epithelial cells, the superficial layer of which becomes cornified At the same time the number of corneal corpuscles is much increased in the propria The infiltration of the substantia propria by pus cells becomes more and more dense, and new blood vessels are formed in the tissue (Fig 4)

These xerotic changes, which, like the ones described above, have been shown to be the result of drying of the cornea, constitute a keratosis in the pathologic sense Another type of epithelial alteration is necrosis, which results from disturbance because of dryness in the nutrition of the cornea The corneal epithelium from the limbus to the center gradually loses its thickness The cells lose their nuclei, and the boundaries between the cells become indistinguishable The epithelium usually becomes infiltrated by pus cells At the same time the propria shows marked edema and diffuse cell infiltration as the result of the condition of the epithelium At last in some cases the epithelium is lost entirely over small areas of the central portion of the cornea, and the substantia propria is left bare In these cases the infiltration of the substantia propria by pus cells becomes very dense, and cellular exudates appear in the anterior chamber and the iris (Fig 5)

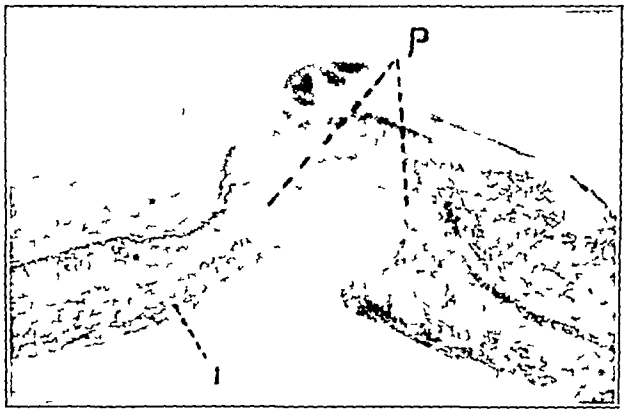

Fig 6—Section through an ulcer (perforated) in the central portion of the cornea which was destroyed the perforation (*p*) is closed with fibrin and pus cells the iris (*i*) is adherent to the cornea

These pictures are similar to those found in cases of keratitis e lagophthalmo in human beings, and are the result of drying of the epithelium of the cornea Very often in the course of the disease the rats' eyes show ulcers which frequently perforate (Fig 6)

As is the case in xerosis and keratomalacia in man, smears from the sore eyes of rats usually contain an enormous number of micro-organisms, such as the streptococcus, staphylococcus, pneumococcus, xerosis bacillus, and gram-negative bacilli, and cocci None of these, however, can be shown to have a specific relation to the disease Paraffin sections were made of eyes

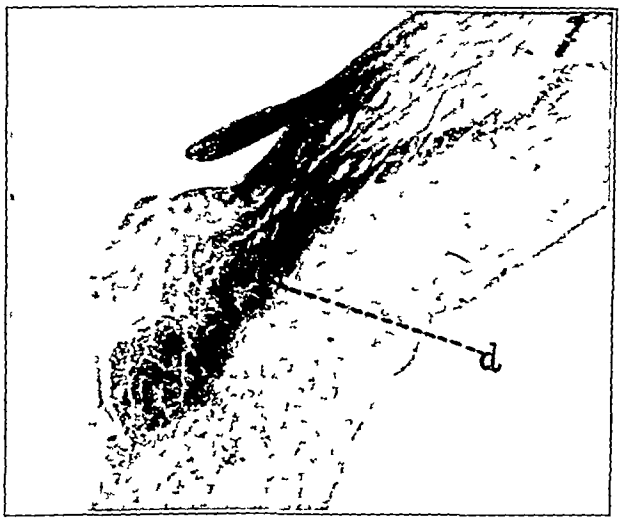

Fig 7—Section through a corneal ulcer showing necrosis of the upper layers the necrotic area is surrounded by a line of demarcation (*d*)

from different cases, normal and diseased, and these were stained with Gram-Weigert's stain and thionin to show, respectively, the gram-positive and gram-negative organisms The study of these sections reveals that, unless there are corneal ulcers, no invasion by bacteria of the cornea or conjunctiva takes places Enormous

8 Leber Theodor Arch f Ophth **29** 225 1883

numbers of cocci were to be seen on the surface of the ulcers. Where the epithelium is lost, the propria becomes necrotic and the necrotic area is surrounded by a line of demarcation. Sections stained with thionin show gram-negative bacilli deep in the corneal tissue beyond this ring of infiltration. The same conditions obtain in the so-called keratomalacia of man (Fig. 7). The study of this material indicates that the changes of xerosis of the conjunctiva and cornea are not the result of bacterial invasion, but that, on the other hand, ulceration of the cornea in these animals is due to infection, and that the infection is secondary to the primary changes I have described.

Many observers have reported that in many of their animals the eye disease was apparently unilateral, and that it was not produced at all in some rats. The histologic study of my material shows that at a period during the feeding of a deficient diet the conjunctiva in both eyes of all animals undergoes the microscopic changes of xerosis. Eyes which show these changes in the conjunctiva may be apparently intact on clinical examination, since the cornea is apparently normal.

In a later paper I shall discuss the relation between the deficiency of fat-soluble A in the diet and the dryness of the conjunctival sac, and I shall describe the defects in the normal secretory mechanism which result in the desiccation of the cornea and conjunctiva.

SUMMARY

The eyes of rats on diets deficient in fat-soluble A show xerosis conjunctivae and xerosis corneae (xerophthalmia). Xerosis is the essential change and is caused only by the dryness of the tissue. The ulcers of the cornea (keratomalacia) are secondary, and are due to secondary infection by micro-organisms.

MUSCLE INTERPOSITION

A CAUSE OF DELAYED UNION IN FRACTURE OF THE FEMUR *

F. C. KIDNER, M.D.
AND
CHARLES B. LAKOFF, M.D.
Attending Orthopedic Surgeon and Assistant Resident Surgeon Respectively, Receiving Hospital
DETROIT

Stimulated by the demands of the war, methods of treatment of all fractures have vastly improved during the last few years. With these improvements of methods worked out by experts, there has been a gradual raising of the standards of results demanded by the general public. Insurance companies, state compensation boards, employers of labor, and the injured men themselves are beginning to inquire more and more closely into the underlying reasons for prolonged or permanent disability following fractures. They are beginning to feel that most fractures should leave behind little or no disability, instead of feeling, as they used to do, that serious fractures must produce cripples.

These changes have thrown an added responsibility on all who essay to treat fractures. They have made it more and more difficult for the general practitioner or the busy general surgeon to care for fractures, and have led to a growing tendency to the establishment of fracture clinics directed by experts, and to the attempts of employers, and the insurance companies, to place their fracture cases in the hands of men who have made fractures their especial care.

All this is particularly true of fractures of the femur. These, above all others, require a large amount of apparatus, a knowledge of many methods of treatment, an especially trained personnel, and ingenuity, if a sufficiently high percentage of perfect results is to be obtained. These requirements are too great to be found in the home or to be given the patients scattered through the wards of the general hospital. They can be found only when considerable numbers of patients are grouped in properly equipped wards under the continuous care of an especially trained force. Whether the man in charge of this force is a general surgeon or an orthopedist makes little difference, if we assume that the general surgeon has the time and patience to devote to the necessary detail and that the orthopedist knows how to operate. It is only by the grouping of cases in such surroundings that we are going to be able to satisfy our public, and it is only thus that improvements in treatment and analysis of error will lead to ultimate standardization and perfect results.

Thorough belief in the foregoing statements justifies us in presenting a small group of cases which call attention to one of the causes of unsatisfactory results in fractured femur, which has received comparatively little attention. This is the interposition of muscle between the ends of the fragments. The cases are from our fracture service at the Detroit Receiving Hospital, a city institution which cares only for the poor, except in emergency, when patients from all walks of life are accepted. In such an institution only the victims of accident who are poor remain under its roof till the final result is obtained. Those who are well-to-do and who come under the employers' liability act are removed as soon as possible to the care of their private physician or to other hospitals. Thus it is difficult to follow all cases to their final results.

From January, 1921, to April, 1922, there were treated in the fracture service a large number of fractures of the femur. Seventy-one of these patients survived their injuries or remained in the hospital for more than one week. All of the seventy-one stayed in the hospital long enough to provide records which will show the final results. These results will be made the subject of a later paper. All of the seventy-one were treated primarily by some modification of Balkan suspension and Thomas splint, with adhesive tongs or Steinmann pin traction combination, with or without prompt active mobilization of the adjacent joints. So far as we know, these are the methods used in all the large fracture clinics, except when some individual patient has insisted on some special operative procedure. In the seventy-one cases, open operation was done for only three reasons: (1) interposition of muscle tissues between the fragments, (2) for debridement of fresh compound fractures, and (3) for previously existing sepsis in cases treated elsewhere before entrance to the hospital.

Of the first class, interposition of muscle, there were six cases. This, according to accepted standards, is an extraordinarily high percentage. It is certainly high if we compare it to fractures resulting from war wounds. In a very large number of war fractures of

* *Read before* the Session on Orthopedic Surgery at the Seventy-Third Annual Session of the American Medical Association, St. Louis, May, 1922.

the femur, both fresh and old, which came under my personal observation overseas and later in this country, I saw only one in which delayed union resulted from this cause This particular case was that of a soldier whose femur had been broken by the kick of a mule and not by a true war wound In talking with other surgeons, I have found that their experiences coincide with mine The reason for the fact that muscle interposition figured rarely in the healing of war wound fractures of the femur, we believe to be twofold 1 The high velocity rifle or machine gun bullet did not displace the main fragments to any great extent 2 The shell wounds which did cause much displacement were always accompanied by great damage to soft parts which required immediate exploratory operation and direct replacement of the bone

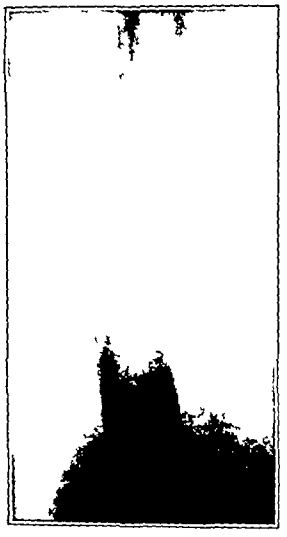

Fig 1 (Case 1)—Overextension but persistent displacement

In civil life, however, most of the forces which cause fractures of the femur involve great lateral or twisting displacement without necessarily causing large, open wounds Such forces are the fall from a great height, the automobile smash, and the crush under heavy weights They displace the fragments largely, thus giving the muscle masses an opportunity to slip between them and be held there by their own elastic quality

All of our cases, of which a brief protocol follows, were the results of automobile injuries, or falls from heights, etc

REPORT OF CASES

CASE 1—H P, aged 20 received a simple fracture of the middle and upper third of the right femur in an automobile collision Jan 22, 1921, roentgen-ray examination revealed an outward and forward displacement of the upper fragment, with shortening Three days later the shortening was overcome, but the upper fragment was still displaced as before Two weeks later the shortening was completely overcome, and lateral alinement was good, but anterior displacement of the upper fragment persisted One month later, the shortening was overcorrected Five days later the same condition existed Six weeks later there was increased anterior displacement of the upper fragment March 17, there was no union and anterior displacement persisted Operation was performed through a lateral incision There was no callus the whole body of the biceps was interposed between the fragments and held by jagged fragments of bone The muscle was freed whereupon reduction of the fragments became easy They were held by kangaroo tendon A plaster cast was applied Convalescence was very slow, bone formation being delayed There was recurrence of outward bowing In February, 1922, union was firm with outward bowing There was three-fourths inch shortening The knee had 35 degrees of motion

CASE 2—M Y, a man, aged 31 sustained a simple fracture of the middle third of the right femur by falling from a scaffold May 23, 1921, roentgen-ray examination revealed the upper fragment displaced anteriorly with some shortening Four days later the shortening was overcome, but anterior displacement of the upper fragment persisted June 10 lateral alinement was good and there was no shortening, but the upper fragment was still displaced anteriorly June 23, a mass of muscle tissue between the fragments was freed The ends were brought together easily and held with kangaroo tendon Slow convalescence ensued, not due to sepsis but to mental and circulatory disturbances The wound healed by first intention, but the fragments slipped because of the patient's violence August 3 there was no union, and there was forward displacement of the upper fragment Since then the patient has been treated at another hospital with a Lane plate, but nonunion persists The fragments did not unite ultimately for reasons outside the muscle interposition

CASE 3—B T, a man, aged 33, received a simple fracture of the middle and lower third of the left femur by a fall from a scaffold Oct 1, 1921, roentgen-ray examination revealed persistent backward displacement of the lower fragment to a mild degree At the end of eight weeks of treatment, including manipulation under an anesthetic, no callus had formed In an open operation, November 22, a mass of muscle between the fragments was freed with great difficulty The fragments were held with kangaroo tendon A plaster spica was applied Two weeks later they slipped out of position in spite of the plaster December 20, a Lane plate was applied It was removed in five weeks Position was perfect but there was no bony union In April, 1922, union was gradually forming

CASE 4—L M aged 21, received a simple fracture of the middle third of the right femur in an automobile crash Roentgen-ray examination Nov 28 1921 revealed a fracture of the upper third of the right femur The lower fragment was displaced slightly to the inner side and posteriorly There was slight shortening A roentgenogram taken December 8 ten days later, in the anteroposterior position, revealed the alinement as being very good A lateral view disclosed posterior displacement of the lower fragment There was no shortening A roentgenogram, December 28 five weeks after the injury revealed no union and no shortening Posterior displacement still persisted Operation Jan 3 1922 revealed the lower fragment displaced backward with separate fragments between it and the lower end of the upper fragment Large muscle bands were found intertwined among the fragments holding them apart These were cleaned away, and anatomic reposition of the fragments was obtained A Gallie beef bone plate held the fragments well Convalescence was slow, callus formation was delayed but this may have been due to the fact that the patient was pregnant May 9, a roentgenogram disclosed a large amount of callus Position was good The patient was up and about A caliper splint was employed

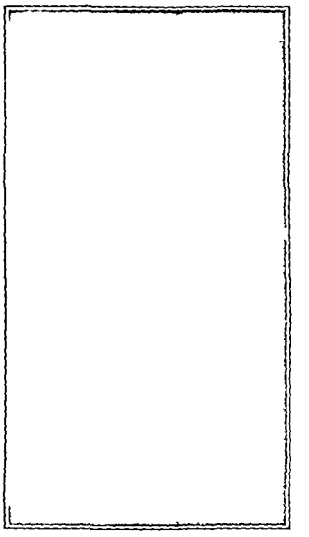

Fig 2 (Case 1)—Reduction after operation for removal of interposed muscle

CASE 5—G B, a man, aged 27 received a simple fracture of the lower third of the left femur Roentgen-ray examination, March 21, 1922, revealed a transverse fracture of the left femur 4 inches above the left knee joint The lower fragment was displaced posteriorly, with about one and one-fourth inches overriding A roentgenogram March 27, revealed the lower fragment still considerably displaced posteriorly At operation March 30 the lower fragment was found displaced backward into the popliteal space It was held there by a dense band of fascia and a tendon of the semitendinosus It was freed with some difficulty and brought forward into perfect apposition with the upper fragment It was held by a Gallie beef bone plate and screws A roentgenogram April 4 revealed good position Another, taken May 11, revealed a considerable amount of callus but the bone plate did not hold firmly There was forward and inward bowing This was easily corrected by lateral and longitudinal traction

CASE 6—M H, a woman, aged 23, entered the hospital, Oct 27, 1921, with a simple fracture of the lower third of the left femur The lower fragment was displaced inward and backward October 18 a roentgenogram revealed the lower fragment still displaced posteriorly and inward There was no apposition October 25 a roentgenogram revealed the same position Shortening had been entirely overcome November 15, the patient was operated on at another hospital Muscle interposition was cleared A Lane plate was applied Union was prompt

CONCLUSIONS

1 If the fragments of a fracture of the femur are not brought into actual bony contact, as shown by the roentgenogram taken in two places, by properly applied traction within three or four days, the case should be viewed with suspicion

2 If specially worked out methods are not immediately thereafter successful, manipulation under an anesthetic should be employed This attempts to disengage the fragments from the muscle Such disengagement can usually be recognized by the clean, clear-cut rubbing of the fragments on each other

3 If, after such manipulation and the reapplication of traction, apposition is absent at the end of two or three days, as disclosed by roentgen-ray examination, open operation should be undertaken

4 At open operation, the muscle or fascia bands must be cleaned from the fragments and good apposition obtained If this apposition is of the end-to-end, interlocking type, then only external fixation splinting is necessary If there is a tendency of the fragments to displace again, some solid forms of internal splint must be used Gallie's beef bone plates or Magnusen's ivory plates and screws or pegs will usually suffice Both are more simple of application than Albee's grafts When they will not hold, metallic plates or bands are occasionally necessary

ABSTRACT OF DISCUSSION

DR WILLIAM R CUBBINS, Chicago I have never seen muscle directly between the fragments of bone when the limb has been extended on a Hawley table The tension made in extending the limb will make the muscles taut, so that while there may be a few ragged fragments of muscle tissue between the ends of the bone, there is not sufficient quantity of muscle between the bone to interfere with union It is well to remember that a little muscle tissue subjected to pressure will rapidly disappear In my opinion, the greatest catastrophe in cases of fractured femur is an operation and infection Disability will continue from six months to six or seven years, fragments of bone being discharged at intervals If the wound is clean and a foreign body is inserted, the area surrounding the site of implantation has an increased amount of heat, which can easily be detected by the examining hand Some persons do not pay much attention to this heat, but a sensitive individual has sufficient cause for claiming disability and the industrial boards before which I have appeared believe this to be sufficient cause for disability When a surgeon is forced into an operation and a plate must be used, by all means use a long, strong plate, with plenty of screws to insure stability, and remove the plate when union has been obtained In my opinion there is no difference in the degree of insult to tissues from steel, ivory or boiled bone They are all foreign bodies I have not been able to see any difference in the degree of insult to tissues by screws through the medullary cavity or merely into the cortex An autogenous bone graft should always be used when possible, and this graft should be made to fix the fragments without the addition of any foreign body Intramedullary bone pegs act well in young persons, very poorly in the aged If an infection occurs with an autogenous bone graft, it is not uncommon to see the bone graft live in spite of the infection My results in treating fractures of the femur by conservative methods during the last three years have been so satisfactory that I sometimes doubt whether I will ever employ an open operation

DR C B FRANCISCO, Kansas City, Mo Dr Kidner limited the indications for open operation to three particulars muscle tissue between the fragments, debridement and sepsis There is one guide in this connection that has helped me and that is, that usually there is a comminution of the fragments and a fragment of bone is knocked across to the opposite side, carrying with it fascia or muscle tissue which is interposed between the fragments I think that one should, as Dr Kidner says, determine this factor reasonably soon because the delay in waiting until union should occur is a great hindrance to throwing out of the callus, and, as he stated, those cases that have gone along for six or eight weeks and were then treated by operation showed a definite delayed union I think also it is very much easier to reduce cases if one tries traction continuously I think the more we try the fewer the number of cases in which open operation is required

DR PHILIP H KREUSCHER, Chicago In the management of any other fracture, the personal equation of the surgeon comes into play Some of us can get very good results with external fixation methods and some can get better results with internal fixation We cannot lay down any law saying one must use Parham-Martin bands, Lane plates or any other appliance in a given case We have been criticized for making walking hardware stores out of our patients because we put in too much metal In a way the criticism is justified I sometimes think we go around looking for fancy splints external and internal, which are unnecessary, when we could use the simpler methods already at our disposal There is a definite indication for the Parham-Martin band, when there are two or three fragments to hold together In the ordinary spiral fracture, it is also of value We should use the Lane plate more than we are using it Some of us do not use the Lane plate properly In the first place, we do not put it in cleanly, the screws become loose, the blood clot becomes infected and the plate has to be taken out If we keep our fingers and the fingers of our assistants out of the wound we are going to do that operation cleanly If we tear muscles we are going to have a certain amount of postoperative trauma and postoperative heat If we expose the bone by following a line of cleavage and do not use heavy retractors but use instead the Farr spring retractors when we are putting on a Lane plate, we will get better results with less trauma Do not try to put it under the periosteum Do not try to put a rectangular screw into a triangular drill hole Use the Sherman screw that will fit down in the hole in the bone and you will have little trouble I disagree with Dr Cubbins when he says that transplants are indicated for fixing the fragments in place I do not believe they stabilize the fracture In the second place, I believe it is too excessive an operation when you have so many other methods you can employ

DR H D WOOD, Fayetteville, Ark I use an improved Hodgen splint It is a splint that can be used in transporting the patient from the place of injury to the home or hospital with as much or more comfort than when the Thomas splint is used I treated my first case of fractured femur more than fifty years ago As Hodgen said 'If you put the fractured limb in a swing and make slight continuous extension, the muscles will relax and permit the fragments to fall in place" He also said, 'When you put your patient's limb in this type

of splint or swing, motion will occur at the place of least resistance, which is the hip joint" I have found that to be the case I have found it a convenient way to treat a compound fracture of the femur when there is an abscess discharging pus You can release one of the bands coming under the limb and dress the wound without disturbing the fracture

DR P B MAGNUSON, Chicago I think Dr Kidner has expressed the views of most of us when he said that he had tried all methods and none of them worked all the time I think most of us who have done fracture work fully appreciate that We condemn the Lane plate and the ivory plate and the bone plate, but when we operate we ought to have them all handy so that we can use whatever is necessary for the case We cannot tell from the outside what we are going to have on the inside I disagree very materially with Dr Cubbins' statement that the Lane plate does not cause any more traumatism or irritation than bone or ivory In the first place, I do not think that it is proper from a purely mechanical standpoint In the second place, those of you who have taken out Lane plates know that many of them have a collection of serum about them I disagree with Dr Kreuscher that the infection is primary Many of them show a little swelling and a seepage of fluid six weeks after Dr Cubbins took out a plate six years ago that Mr Lane put in eight years ago, because it was bothering the patient It is true that all these things loosen up You can say what you like about dead bone, ivory or autogenous graft, they all loosen up at some point in the procedure After that they may tighten up if they are not warped, but I never saw a Lane plate tighten up after it was once loosened If you were to be operated on, you would not care to have to undergo a second operation later to take out something that was put in to do the first job, when you could have had something put in to stay

DR FREDERICK C KIDNER, Detroit I must disagree with what Dr Cubbins says about muscle interference in fractures with traction I have operated and found muscle intervening no matter how hard I pulled even on the Hawley table I agree we should use every effort to get the fragments together without open operation As to bone grafts, I do not think they are better than any other means of internal fixation They do not give the rigidity in difficult cases that metal, ivory or beef bone often does They are very useful, perhaps, in ununited fractures The longer we wait in these muscle interposition cases the slower will be the convalescence following the operation Therefore, I am learning to try to recognize these cases and get my open operation done by the end of a week or ten days The matter of Lane plates becoming septic is to my mind dependent on the surgeon only I do not believe it is any wiser or more necessary to operate on bone with long instruments without the use of fingers than it is in the abdomen I think the resistance of muscle and bone to infection is just as great as the resistance of the abdomen I still believe that the use of gloved fingers does less harm and causes less traumatism than does a strictly instrumental technic

Complete Hospital Data Lacking—In no American city of any size is it possible to give the total number of cases admitted to the hospitals, both public and private, the diseases for which entrance was sought, the age and sex distribution of the patients, the duration of treatment and the result of the treatment It is a blemish on the excellent work done by hospitals that this phase of their activities has been left undeveloped almost without exception in the United States—H Emerson, *Hosp Soc Service* **4** 271 (Nov) 1921

A COMPARATIVE STUDY OF ETHMOIDAL AND SPHENOIDAL OPERATIONS*

J J SHEA, M D
MEMPHIS, TENN

The appreciation that the posterior ethmoidal cells and the sphenoidal sinus are the causative factors in many of the optical nerve disorders has centered attention on this region Formerly, the anterior ethmoidal cells held the center of the stage in our attention because of their relationship to the frontal sinus The older operations were so designed that the anterior cells were first attacked and were more thoroughly exenterated at the expense of an uncertainty of thoroughness in the posterior region If the sphenoidal sinus and the posterior ethmoidal cells are the important factors, then the successful operation must be based on thoroughness in their exenteration In like manner, the curet, guided by the sense of touch, must give way to the trustworthy biting forceps, controlled by the sense of sight The fundamental law of safe ethmoidal and sphenoidal surgery is to work by sight only, avoiding tearing by accomplishing each removal with a clean bite It is intended to compare the intranasal operations and not to consider the radical operations

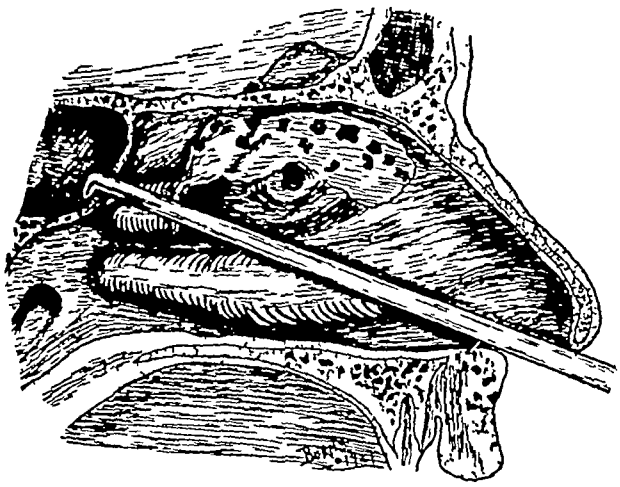

Fig 1—Fleshy posterior tip of the middle turbinate being used as a landmark for the puncturing of the sphenoidal sinus

ANATOMY

The ethmoidal and sphenoidal sinuses are so closely articulated as to be considered one structure The division between the anterior and posterior cells cannot be made out surgically, nor can the posterior cells be completely exenterated without removing the pars ethmoidalis, which will open the sphenoidal sinus The middle and superior turbinates are only specialized portions of the ethmoidal bone The optic nerve is in close relation with the lateral and superior aspect of the sphenoidal sinus and usually with the postero-external angle of the last posterior ethmoidal cell Its course forward in the orbit carries it farther away from the inner orbital wall the farther it goes forward, so that it is increasingly removed from the possibility of contact with the anterior ethmoidal cells Hence, in disturbances of the optic nerve, the usual or logical site of a causative nasal lesion is in the sphenoid or posterior ethmoidal cells [1]

The middle turbinate is so situated that its posterior end is anterior to the sphenoidal sinus and is a reliable landmark in locating the sinus

There is a type of spheno-ethmoidal labyrinth similar to the persistent infantile type of mastoid, that is, the cells are small and their walls firm, and this condition may be due to an arrested development When this

1 Loeb H W and Wiener Meyer Ann Otol Rhinol & Laryngol **30** 74 (March) 1921

type is encountered, the pathologic condition present is chronic, and the postoperative healing is slow

PHYSIOLOGY

The special sense of smell is a subject for consideration in ethmoidal surgery The protection of the membrane lining the superior turbinate and the septum opposite to it will preserve this sense It is very embarrassing to the surgeon for the patient to lose this sense but this will happen if the membrane lining the superior turbinate is totally destroyed

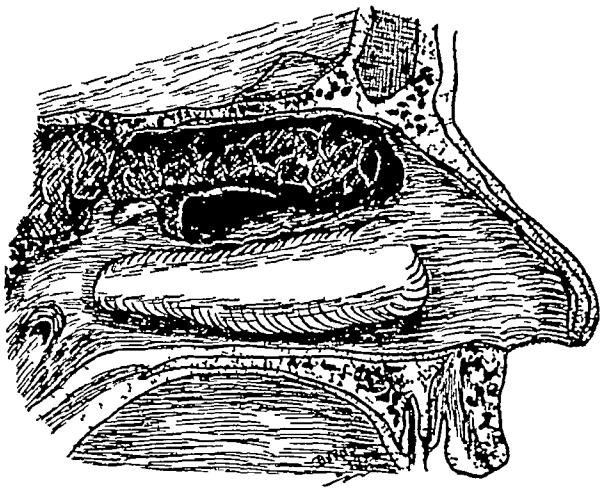

Fig 2—Completed operation thoroughness of the exenteration of the posterior ethmoidal cells

OPERATION

A description will be first given of a composite operation that has for its advantage a greater chance of thoroughness in resecting the anterior wall of the sphenoid and exenterating the posterior ethmoidal cells, and then a comparison of its advantages with the usual textbook operation will be considered The operation is based on the good points of operations discussed Through the courtesy of Dr Loeb I will use for illustration and description the operations as outlined in his book [2]

The patient, having been thoroughly anesthetized (local preferred), is placed in a semiprone position or upright, with an assistant supporting the head The position assumed by the patient should not be allowed to distort one's surgical anatomy The middle turbinate is completely removed This will always leave a fleshy tag at its postero-inferior attachment The sphenoidal sinus is situated immediately posterior to this tag, and at all times this tag may be used as a landmark in orientating oneself in this region

By passing the sphenoidal punch alongside this tag the sphenoidal sinus can be directly entered at its safest point (the inferomesial aspect) The pars nasalis is resected with due reverence to the position of the posterior branch of the nasopalatine artery Yankauer has given us a method of attacking this vessel and eliminating it as a complicating factor This is detailed under his operation The resection is carried outward and, by the removal of the pars ethmoidalis, the posterior ethmoidal cells are entered If there are any atypical ethmoidal cells surrounding the sphenoid or any extending laterally, they are easily entered and their partitions removed A small piece of gauze is now placed so as to fit against the nasopharynx and lessen the amount of blood that will run down into the throat The exenteration of the ethmoidal cells is accomplished with suitable biting forceps, starting from behind and working forward at the level of the attachment of the middle turbinate The cells are thus reduced in layers from above downward The cells which lie above the attachment of the middle turbinate are removed by using the forceps in such a position that the longer blade is toward the median line This will prevent injury to the cribriform plate The mucous membrane covering the uncinate is reduced, and with suitable forceps the anterior cells are removed Occasionally it will be necessary to use a curet in this anterior position to expose the foremost cells, but their removal is accomplished with biting forceps If there has occurred a hypertrophy of the ethmoidal cells, to such a degree that they obstruct the vision of the posterior region, then the obstruction must be reduced before the more delicate posterior surgery is undertaken In like manner, if the septum is deflected and will interfere with free instrumentation at the time of operation or in the after-treatment, it should be resected

As all the operating is done by sight, the field must be kept clean of blood The use of a suction tube will expedite matters At first we used a glass drinking tube by attaching it to the suction side of the ether suction machine, but it was found to be too large to enter many of the sphenoidal cavities, so Mr V Mueller made us a removable tip for the instrument described by Walker

Yankauer [3] recommends irrigation of the nares with iced saline solution when the action of the epinephrin has died away

PRATT'S OPERATION

Dr J A Pratt [4] presented in 1919 an operation in which the middle turbinate was allowed to remain His description of the technic is given below

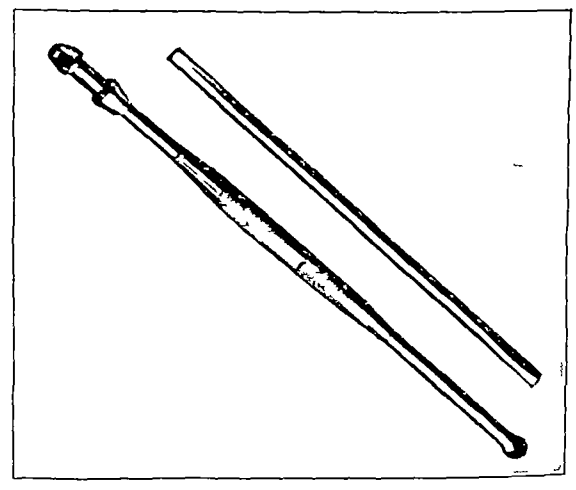

Fig 3—Suction instrument for intranasal use made by modifying the tip of the instrument designed by Walker

The anterior cells are opened with the nasal cutting forceps biting just under the anterior end of the middle turbinate, pointing toward the corner of the eye and continuing backward and upward as long as there is soft bone encountered

We take the straight end of the curet and, with a

and the sphenoid cell have been opened, their entire inner walls and the partitions which separate them being completely removed and all converted into one single cavity." The sphenoid is attacked early in the operation and its anterior wall resected, exposing any hidden posterior cell. Yankauer localizes his roof by utilizing the upper limits of the sphenoid or the posterior ethmoidal cell. "The anterior cells are opened from behind forward, until the anterior limiting line has been reached which is the rounded border of the nasal process of the superior maxilla."

Comment.—This operation is full of wisdom and, if followed, will render favorable results and be a source of benefit to the chronic ethmoidal cases.

ABSTRACT OF DISCUSSION

DR. FRANK L. DENNIS, Colorado Springs, Colo.: Dr. Shea has emphasized that it is much better to work from behind forward, because one has the advantage of seeing what one is doing. The method of proceeding from before backward has the disadvantage of obscuring the field, not only by blood, but the entire front of the nose is filled with a mass of debris. Another point he brought out that is of importance is that it is necessary first to create a passageway for the operation. In other words, if the septum is deflected to one side, if the anterior end of the turbinate is enlarged, one must first create room for operating. The impression is given that the ethmoid operation does not amount to much. That is not true. There is too close a relation of too many important structures for any one to operate in the ethmoid region without the greatest care and without being able to see what he is doing. Not only should a roentgenogram be made of the sphenoid and ethmoid, but the nose itself should be studied beforehand. Dr. Shea did not say anything about hemostasis or anesthesia. Both are very important in the success of the operation. Another point is the importance of the after-care of these patients. The general idea is to leave in place as much as possible of the lining membrane, but whether that is practicable in many cases is a question in my mind. Many times one must take out much more membrane than one thinks desirable. Therefore, I think that in all these ethmoid operations the importance of the after-care should not be overlooked.

DR. T. E. CARMODY, Denver: The one point we must keep in mind is that we are coming to recognize the value of controlling hemorrhage. The nasal operations that we saw up to two or three years ago were bloody operations. The control of hemorrhage as brought out by Yankauer and Shea is simple and will help a great deal. I have found that an ordinary large sized eustachian catheter will answer the same purpose as the suction apparatus or Shea's instrument. In some cases the middle turbinate can be left but we ought to be careful about leaving it when there is marked enlargement in the middle turbinate, because it will close the space and we shall be unable to take care of after-treatment as well.

DR. JOHN A. CAVANAUGH, Chicago: It is a difficult proposition to make roentgenograms that show positively whether the sphenoid is a definite size unless one injects it. I have injected these sphenoids with barium solution suspended in malted milk. I was surprised at the variations these sinuses revealed. The ethmoids on one side are always superimposed on the ethmoids of the opposite side, and it is difficult to separate them in the picture. In the last year I have been cocainizing the nose and introducing small films into the nasal cavity between the middle turbinate and the septum, placing markings on the anterior wall of the sphenoid and various points of the ethmoids and along the lower edge of the middle turbinate. This work is not completed. I hope that something will come of it. Regarding the sphenoid operation, and the picture showing the removal of the anterior wall of the sphenoid, some of you may have seen the burr I devised for removing this wall. I have not been able to find biting forceps to take down this wall of the sphenoid completely. But with my burr one can remove the entire wall and floor, which gives perfect drainage.

DR. EDWIN MCGINNIS, Chicago: When Dr. Mosher first brought out the anatomy of the ethmoid region with complete exenteration, curettage and cleaning up afterward with biting forceps, it seemed that we had reached very satisfactory results in operative surgery. A year later Dr. Shambaugh gave some data of exenteration which seemed to emphasize the result. During the last year, however, I have had three or four patients who had had complete exenteration of the ethmoid and who had reinfection of the cells that remained. If we could exenterate the sphenoid and antrum, I think that exenteration of all the cells would be the ideal operation. Of course it is impossible to eradicate the antrum—Killian used to obliterate the frontal, but it is impossible to eradicate the sphenoid. One gets very enthusiastic about this thing, because if one can clear up the olfactory region in the narrow space between the middle turbinate and the turbinal plate, very often these patients will recover. A high septum operation will clear it up in many cases. Many of the patients do not do well. Study of the ethmoid region will reveal that the middle turbinate divides the two groups of cells, anterior and posterior and the posterior cells are larger and have larger openings. But it is hard to examine these posterior cells the anterior group are easy to observe. I proposed a drainage operation two or three years ago. I made an incision into the anterior ethmoid cells up to the frontal sinus extending this through the posterior cells and back to the anterior wall of the sphenoid. Dr. Yerger gave the statistics in regard to infection of the sphenoid at the county hospital in the cases that came to postmortem. The sphenoidal sinus was the least infected of all of the nasal accessory sinuses. If one drainage operation does not do any good, one can do another, and, if the second drainage operation does not give results, one can then exenterate. For two years I have not disturbed the middle turbinate and have not exenterated the ethmoid labyrinth, and the patients do just as well as those who have had exenteration of the ethmoid.

DR. FRED J. PRATT, Minneapolis: I want to protest against removing the middle turbinate. The middle turbinate is a good thing to have as a guide during an ethmoid operation. The openings in the cribriform plate are between the middle turbinate and the septum, and if one removes the turbinate one opens an avenue for infection into the brain which can be avoided if one keeps the middle turbinate and works under it. Speaking of cleaning out the ethmoid, every one knows that there are accessory cells. Often we cannot find these the first time. The only thing to do, after exenterating the ethmoid, if the case does not clear up, is to go back and find out where the trouble is. The doctor spoke about not being able to keep the space open under the turbinate if it is left in place. Granulations form even if one removes the turbinate, and if the turbinate is left, all that is necessary to do is to follow around the opening and bite off the granulations. One can do this just as well by leaving the turbinate as by removing it. Another thing tending to prove that the middle turbinate is of some use is that one will find in cases in which the turbinate was removed years before that Nature has put soft hypertrophies on the lateral wall and septum trying to narrow the space. I think that this is proof that the middle turbinate is of some use.

DR. JOHN J. SHEA, Memphis, Tenn.: It requires from six to twelve months to obtain permanent results after an exenteration of the ethmoids in many of the cases and during this period the patients should be treated carefully. Unless the sight is at stake an ethmoidal case should be treated a month or two before operating, unless gross pathologic conditions are present. The discharge will change its character after the cells have been exenterated but will not cease entirely. If the discharge remains purulent, scabs will be formed, but the cases are not troubled by dryness, as one would expect. A method of outlining the sphenoid of one side, when inspection fails to be satisfactory, is to insert the Holmes nasopharyngoscope into the other sphenoidal cavity

close, to sanction such radical procedures *en masse* Then, too, there are so few perfect labyrinths, and the anatomic variations are so great, that the method is limited to only selected cases, in the hands of a very few surgeons

HAJEK'S OPERATION

Hajek resected the middle and superior turbinate with his hook and reduced the anterior wall of the

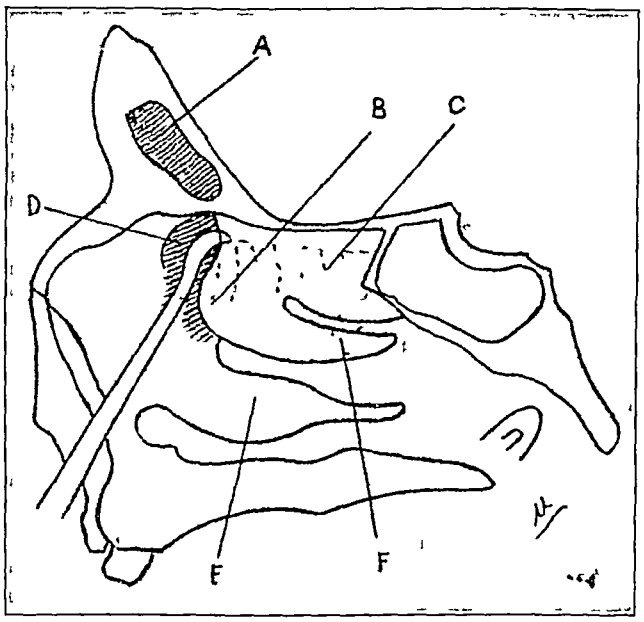

Fig 6.—Mosher s operation exenteration of the ethmoidal cells from before backward

sphenoid and the posterior ethmoidal cells with the same hook, by inserting the hook posteriorly and drawing it forward and removing the shreds with forceps [1]

Comment.—This was the first operation which attacked the sphenoid primarily, and which worked from behind forward

SLUDER'S OPERATION

Sluder's technic is an improvement on that of Hajek's, and the hook is replaced by a Sluder ethmoid knife, so constructed that the cutting edge is turned at right angles to the shaft and sharpened so as to cut on the pull, with the lower part of the shaft supporting a sharpened edge The middle and superior turbinates are removed with the knife The sphenoid is attacked directly, and the pars nasalis and the pars ethmoidalis are resected, thus exposing the posterior ethmoidal cells The ethmoidal capsule is resected by a series of strokes from behind forward, and working away from the roof With suitable forceps, the fragments are removed and the field is made surgically clean [2]

Comment.—The same may be said of this method as of the method of Hajek, that the sphenoid and the posterior ethmoidal cells may be thoroughly exenterated Early attention to the posterior region insures the success of the operation

REAVES' OPERATION

Reaves,[6] in 1919, emphasized the value of sharp biting forceps, and the fact that the only acceptable operation is one that completely exenterates all the cells and resects the anterior wall of the sphenoid He also calls attention to the fact that the mucoperiosteum curetted or stripped by dull forceps from the roof and wall will be covered over by granulation tissue, which becomes scar tissue or a boggy mass to harbor infection Reaves removes "the middle turbinate, the vertical plate of the ethmoid with the superior turbinate and lower half or two thirds of the ethmoid cell with his ethmoid knife," the roof is orientated, and "then follows the removal of the ethmoidal cells forward and backward or vice versa with forceps adapted in size to engage the cells which are even higher than the nasal roof"

Comment.—Reaves has given us not only a method but also the necessary instruments to accomplish our purpose He also brought out thoroughly the fact that the lining mucoperiosteal membrane should be protected and sufficient time taken to completely exenterate all cells possible of reaching by sight

YANKAUER'S OPERATION

Yankauer, in 1920, gave an encouraging outlook to the modern spheno-ethmoidal operation, and added several very valuable points to its technic The isolation of the posterior branch of the nasopalatine artery as it crosses the face of the sphenoid and by crushing, eliminating it as a complicating factor, is worthy of notice The use of iced physiologic sodium chlorid solution as a douche during the operation to check the oozing after the epinephrin has ceased to act, and

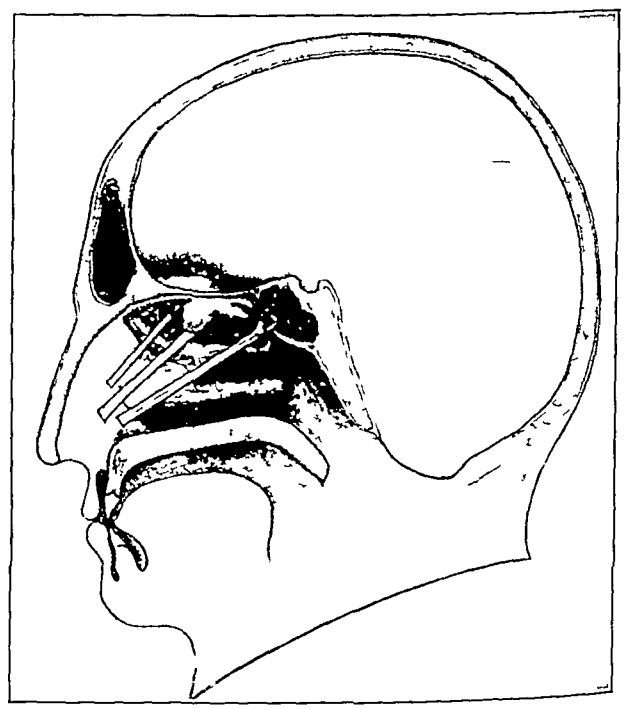

Fig 7.—Reaves operation use of the 15 degree angle ethmoidal forceps in removing the middle turbinate position of the sphenoidal punch while resecting the anterior wall of the sphenoid

the use of bone wax to plug the anterior ethmoidal artery when it is a source of hemorrhage, are worthy of praise Yankauer [3] thus describes a very sensible and thorough operation The middle turbinate is removed with a Holmes scissors and snare "The most prominent cell is attacked with forceps From this point the opening of the cells proceeds in a backward direction until all of the cells of the posterior group

6 Reaves Perry Ethmoidal Operation for Pansinusitis Tr Acad Ophth & Oto Laryngol 1919

and the sphenoid cell have been opened, their entire inner walls and the partitions which separate them being completely removed and all converted into one single cavity" The sphenoid is attacked early in the operation and its anterior wall resected, exposing any hidden posterior cell Yankauer localizes his roof by utilizing the upper limits of the sphenoid or the posterior ethmoidal cell 'The anterior cells are opened from behind forward, until the anterior limiting line has been reached which is the rounded border of the nasal process of the superior maxilla"

Comment—This operation is full of wisdom and, if followed, will render favorable results and be a source of benefit to the chronic ethmoidal cases

ABSTRACT OF DISCUSSION

DR FRANK L DENNIS, Colorado Springs, Colo Dr Shea has emphasized that it is much better to work from behind forward, because one has the advantage of seeing what one is doing The method of proceeding from before backward has the disadvantage of obscuring the field, not only by blood, but the entire front of the nose is filled with a mass of debris Another point he brought out that is of importance is that it is necessary first to create a passageway for the operation In other words, if the septum is deflected to one side, if the anterior end of the turbinate is enlarged one must first create room for operating The impression is given that the ethmoid operation does not amount to much That is not true There is too close a relation of too many important structures for any one to operate in the ethmoid region without the greatest care and without being able to see what he is doing Not only should a roentgenogram be made of the sphenoid and ethmoid but the nose itself should be studied beforehand Dr Shea did not say anything about hemostasis or anesthesia Both are very important in the success of the operation Another point is the importance of the after-care of these patients The general idea is to leave in place as much as possible of the lining membrane, but whether that is practicable in many cases is a question in my mind Many times one must take out much more membrane than one thinks desirable Therefore, I think that in all these ethmoid operations the importance of the after-care should not be overlooked

DR T E CARMODY, Denver The one point we must keep in mind is that we are coming to recognize the value of controlling hemorrhage The nasal operations that we saw up to two or three years ago were bloody operations The control of hemorrhage as brought out by Yankauer and Shea is simple and will help a great deal I have found that an ordinary large sized eustachian catheter will answer the same purpose as the suction apparatus or Shea's instrument In some cases the middle turbinate can be left, but we ought to be careful about leaving it when there is marked enlargement in the middle turbinate because it will close the space and we shall be unable to take care of after-treatment as well

DR JOHN A CAVANAUGH Chicago It is a difficult proposition to make roentgenograms that show positively whether the sphenoid is a definite size unless one injects it I have injected these sphenoids with barium solution suspended in malted milk I was surprised at the variations these sinuses revealed The ethmoids on one side are always superimposed on the ethmoids of the opposite side, and it is difficult to separate them in the picture In the last year I have been cocainizing the nose and introducing small films into the nasal cavity between the middle turbinate and the septum placing markings on the anterior wall of the sphenoid and various points of the ethmoids and along the lower edge of the middle turbinate This work is not completed I hope that something will come of it Regarding the sphenoid operation, and the picture showing the removal of the anterior wall of the sphenoid some of you may have seen the burr I devised for removing this wall I have not been able to find biting forceps to take down this wall of the sphenoid completely But with my burr one can remove the entire wall and floor, which gives perfect drainage

DR EDWIN MCGINNIS, Chicago When Dr Mosher first brought out the anatomy of the ethmoid region with complete exenteration, curettage and cleaning up afterward with biting forceps, it seemed that we had reached very satisfactory results in operative surgery A year later Dr Shambaugh gave some data of exenteration which seemed to emphasize the result During the last year, however, I have had three or four patients who had had complete exenteration of the ethmoid and who had reinfection of the cells that remained If we could exenterate the sphenoid and antrum I think that exenteration of all the cells would be the ideal operation Of course it is impossible to eradicate the antrum—Killian used to obliterate the frontal, but it is impossible to eradicate the sphenoid One gets very enthusiastic about this thing because if one can clear up the olfactory region in the narrow space between the middle turbinate and the turbinal plate, very often these patients will recover A high septum operation will clear it up in many cases Many of the patients do not do well Study of the ethmoid region will reveal that the middle turbinate divides the two groups of cells, anterior and posterior and the posterior cells are larger and have larger openings But it is hard to examine these posterior cells the anterior group are easy to observe I proposed a drainage operation two or three years ago I made an incision into the anterior ethmoid cells up to the frontal sinus extending this through the posterior cells and back to the anterior wall of the sphenoid Dr Yerger gave the statistics in regard to infection of the sphenoid at the county hospital in the cases that came to postmortem The sphenoidal sinus was the least infected of all of the nasal accessory sinuses If one drainage operation does not do any good one can do another, and, if the second drainage operation does not give results, one can then exenterate For two years I have not disturbed the middle turbinate and have not exenterated the ethmoid labyrinth, and the patients do just as well as those who have had exenteration of the ethmoid

DR FRED J PRATT, Minneapolis I want to protest against removing the middle turbinate The middle turbinate is a good thing to have as a guide during an ethmoid operation The openings in the cribriform plate are between the middle turbinate and the septum, and if one removes the turbinate one opens an avenue for infection into the brain which can be avoided if one keeps the middle turbinate and works under it Speaking of cleaning out the ethmoid every one knows that there are accessory cells Often we cannot find these the first time The only thing to do, after exenterating the ethmoid if the case does not clear up, is to go back and find out where the trouble is The doctor spoke about not being able to keep the space open under the turbinate if it is left in place Granulations form even if one removes the turbinate, and if the turbinate is left, all that is necessary to do is to follow around the opening and bite off the granulations One can do this just as well by leaving the turbinate as by removing it Another thing tending to prove that the middle turbinate is of some use is that one will find in cases in which the turbinate was removed years before that Nature has put soft hypertrophies on the lateral wall and septum trying to narrow the space I think that this is proof that the middle turbinate is of some use

DR JOHN J SHEA Memphis Tenn It requires from six to twelve months to obtain permanent results after an exenteration of the ethmoids in many of the cases and during this period the patients should be treated carefully Unless the sight is at stake an ethmoidal case should be treated a month or two before operating, unless gross pathologic conditions are present The discharge will change its character after the cells have been exenterated, but will not cease entirely If the discharge remains purulent, scabs will be formed, but the cases are not troubled by dryness as one would expect A method of outlining the sphenoid of one side when inspection fails to be satisfactory, is to insert the Holmes nasopharyngoscope into the other sphenoidal cavity

and transilluminate the questionable cavity The paper did not deal with the indications for the operations Dr Carmody spoke of the eustachian catheter as a suction instrument The one I improved is the outgrowth of using first a catheter and then glass drinking tubes The latter are the more serviceable

A CONSIDERATION OF ACUTE AURAL DISEASE IN CHILDREN *

A SPENCER KAUFMAN, M D
PHILADELPHIA

Acute infections of the middle ear are met with at all times, but from December to April of each year they are exceedingly numerous, and as surely as they appear in succeeding years they vary in symptomatology and severity In the past season, for instance, the number of cases of acute otitis media was greater than usual, and the severity of the symptoms was out of proportion to the morbidity of the disease

It is indeed surprising how seldom aural examinations are practiced routinely, and it is well to emphasize at the beginning that, when such an examination is made and reveals trouble, and the proper methods of treatment are instituted, we have not only treated the existing condition, but have also applied prophylaxis against permanent loss of function and the dangerous intracranial complications

ETIOLOGY

Considering the causative factors, we find the most common source of acute middle ear inflammation in local infection of the nose and throat, as well as in the general infections in which nose and throat involvement is more or less constant We have but to remember that the mucous membrane lining the nose and throat continues up the eustachian tube, lines the middle ear cavity, attic and mastoid antrum, and forms the internal layer of the tympanic membrane, to realize with what ease infections involving the nasopharynx may, in turn, infect the ear Influenza, measles and pneumonia are the most important general infections, but all of the other exanthemas and acute infectious diseases play important parts In this class of cases, a routine inspection of the ears should be made, as one would examine the chest and abdomen for evidence of new developments Local causes are the infections confined to the upper respiratory tract, such as acute rhinitis and obstructive conditions Anything that interferes with the proper ventilation of the nasopharynx and eustachian tubes is a direct or indirect causative factor Adenoids, by their direct blockage, and hypertrophied tonsils, by the upward pressure exerted on the tubes, are, of course, the most common factors The removal of diseased tonsils and adenoids is the best prophylactic measure at our command in the prevention of aural involvement This is true not only in the acute form but also in the chronic suppurative and nonsuppurative

It must be borne in mind, however, that, while the susceptibility to infectious processes is materially reduced by this operation, the possibility of their occurrence still exists when we have an acute nasopharyngitis, either primary or secondary The vicious habit of teaching children to blow their noses by holding one or both nostrils tightly closed and applying expulsive force should be discouraged as dangerous to the ear Chronic general diseases, such as tuberculosis, syphilis, scurvy, diabetes and nephritis, are often underlying conditions, but, except in the case of tuberculosis, in which we recognize a distinct type of otitis, middle ear involvement is probably due to lowered resistance, rather than to a distinct local manifestation We all must agree that purulent otitis media occurs too frequently during dentition in infants to be a mere coincidence The probable explanation is that, at the time of teething, there is general congestion of the entire mucous membrane of the nose and nasopharynx, causing a blockage of the tubes

PATHOLOGY

The pathology in a direct infection does not vary from that of a condition involving the mucous membrane of any other structure, but there is a distinct difference in that class of cases that might be called secondary infection By that, I mean those in which the eustachian tube is sealed off and the air in the tympanic cavity becomes absorbed With its gradual disappearance, there is an outpouring of mucus, and we then have a condition termed hydrops exvacuo If this fluid remains sterile, it will be gradually absorbed as the inflammation subsides and ventilation of the tympanic cavity is again established This will clear up with proper treatment applied to the nose and nasopharynx, but, if it is of longer duration, active surgical treatment, such as will be spoken of later, must be applied

SYMPTOMS AND TREATMENT

It is well to consider the symptomatology and treatment of the catarrhal and purulent otitis together, because, although we have a distinct disease in the acute catarrhal otitis media every case of the suppurative variety must pass through the catarrhal first No matter how brief this stage may be, it exists nevertheless and the symptoms that present themselves in the suppurative type are, with few additions, exaggerations of those that we find in the catarrhal

First and foremost is the development of pain, which is usually worse at night This varies from a slight discomfort to an exceedingly excruciating earache The ordinary "earache of childhood" is attended by pain which is very severe but of short duration, and little can be seen on examination except, possibly, some redness along the handle of the malleus or of Shrapnell's membrane Tenderness can also be elicited by pressure in front of the tragus and immediately below the lobe An important thing to remember is that, in the acute infectious diseases, there may be an absence of pain, and we often see, during the convalescence, that the temperature goes up for some unknown reason If the ear has not been examined it is not an infrequent occurrence to have a discharge from the external auditory canal as the first evidence of middle ear involvement Symptoms of impaired function, such as tinnitus, are rarely complained of even by older children, although the parents may notice a loss of hearing Fever is always present in the suppurative variety, but is usually absent in the catarrhal, when the etiologic factor is afebrile Two significant symptoms of acute ear disease in infants are the attempt to get the hand up to the side of the head affected and rolling of the head from side to side The latter symptom has been spoken of so much that an occasional diagnosis of ear disease is made without careful examination, and later it is found that this action is due to other causes

* Read before the Section on Diseases of Children at the Seventy Third Annual Session of the American Medical Association St Louis May 1922

Occasionally, actual convulsions, followed by coma, are seen in young children suffering from an acute middle ear condition This is caused by an irritation of the dura through a dehiscence in the roof of the attic, due to an open petrosquamosal fissure With the development of pus, the redness becomes intense, there is bulging of more or less of the entire membrane and an obliteration of all the landmarks, and it is exceedingly difficult to decide where the posterior wall of the bony canal ends and the tympanic membrane begins In a case that was originally sterile, as a hydrops exvacuo, and in which the fluid has become infected or present in such quantity as to cause bulging, we will see a rather faint yellow discoloration of the ear drum, with bulging in the posterior half I wish to emphasize this particular point, as, in a casual examination of the ear, this may possibly appear as a normal ear drum, when one has in mind the more usual picture, with the intense redness or dusky discoloration In this type of case, the cone of light also will often be present, which is likewise misleading Complicating some of the acute infectious diseases, particularly influenza, there are frequently formed hemorrhagic blebs, either on the membrane proper or on the adjacent wall of the canal A mere pricking of these blebs is frequently done, the operator feeling that he is incising the membrane, but procures no relief from the pain and other symptoms

By far the best treatment for acute catarrhal otitis media is rest Accompanying this, eliminative treatment should be given and, if the case is seen early enough, small doses of aconite, and powder of ipecac and opium (Dover's powder) in doses depending on the age of the patient Locally, heat, applied in one of several ways to the tympanic membrane, is by far the best means of relieving inflammation Hot irrigations with physiologic sodium chlorid solution, or just plain sterile water, every two or three hours, will give prompt relief The best method of administering these hot douches is to use an irrigating can with a small glass tip, having the can held not higher than the level of the patient's head when it is in position to receive the treatment This point should be made emphatic to the nurse or attendant The amount of solution used should be from 1 to 2 quarts (liters), and the temperature about 110 F The commonly used 10 per cent of phenol in glycerin is an admirable composition and accomplishes good in three ways (1) by the heat, as all such drops should be thoroughly warmed before instilling into the canal, (2) by the hydroscopic action of the glycerin, and (3) by the anesthetic and antiseptic effect of the phenol The ear should be protected from cold air at all times during an inflammatory process, and I usually advise wearing a light cap with a pad of cotton over the ears

In addition to the general treatment and that applied directly to the ear, we must not forget the source of infection—the nose and throat For this purpose, any of the several drugs that have an astringent action, sprayed or dropped into the anterior nares, will usually accomplish the desired effect My own preference is either a camphor-menthol solution in the strength of 3 grains each to the ounce of liquid petrolatum, or a mixture of cocain alkaloid, 2 grains, camphor, 1 grain, and 4 drops of oil of lavender or rose geranium to the ounce of liquid petrolatum Flushing of the nose, I feel, is liable to scatter the infection into the eustachian tube and the accessory sinuses, but, if the swelling of the mucous mebrane is reduced, the nose will usually take care of its own drainage In my observations, I have found that the colloidal silver preparations which are so commonly used in nasal conditions of this type are more of an irritant and will increase the flow of mucus, and the harm thus done outweighs any beneficial results gained from their antiseptic powers Postnasal irritation can be relieved by local application of the camphor-menthol solution It would be exceedingly advantageous when adenoids and hypertrophied tonsils are present to remove them, but, except in cases due to these causes alone, we must forego this procedure, as it is obviously impossible to operate during the course of an acute infectious disease or in the presence of a general involvement of the upper respiratory tract

When we find that we are dealing with a purulent otitis media or large collection of fluid in the middle ear, there is but one treatment and that is free incision I use the word incision in contradistinction to paracentesis, as a mere puncture will but drain for the time being and will later on probably have the same effect as a spontaneous rupture We must remember that a rupture of the ear drum is not a wound with even edges, and it is not caused by pressure, just as a toy balloon will burst when blown beyond its limit of elasticity, but, layer by layer, the membrane sloughs, and the result is a ragged-edged wound, which is more liable to remain a permanent perforation This operation is preferably performed under general anesthesia, but, unfortunately, many of these conditions arise in bedridden patients in whom the underlying causes contraindicate ether or chloroform (and nitrous oxid is not readily obtainable in private homes), so that we must use a local anesthetic or none at all The local anesthetic that I use is composed of equal parts of cocain, menthol and phenol, the solid drugs being rubbed together to form a syrupy liquid My experience is that the membrane can be incised with no more discomfort to the patient than is caused by introducing a local anesthetic The place to make the incision is over the point of greatest bulging, which is almost always in the posterior part This is also the correct position from the anatomic standpoint, as there is more room between the handle of the malleus and the tympanic ring, and the distance between the internal wall of the cavity and the tympanic membrane is greatest in this quadrant Furthermore, it will give a direct route for drainage from the mastoid antrum Incision should be carried to the floor and slightly curved Following incision, it is of great advantage to remove the secretions from the middle ear by means of a small suction apparatus

I have mentioned that this operation should be performed in all cases of acute suppurative otitis media and in cases in which there is bulging of the membrane from fluid in the middle ear, even though it be sterile, but there is still another important indication, namely, the more violent cases of acute catarrhal otitis media, arising during the course of acute infectious diseases Under these circumstances it is safe to incise the membrane without waiting for bulging, as we can be definitely certain that infection will occur and spontaneous rupture may take place in an incredibly short time

The after-treatment is of the utmost importance After the membrane has been incised, the ear is best left alone until the discharge becomes purulent or very profuse (which usually takes place in twenty-four hours), and then irrigations should be started For this purpose, I prefer a 1 5,000 solution of mercuric

chlorid, more for the purpose of insuring a sterile solution than for the antiseptic effect on the suppurative process The object of the irrigation is two-fold (1) it reduces inflammation by the application of heat, and (2) it keeps the canal clear so that the flow of secretion from the middle ear will not be impeded When the patient is visited by the physician, the canal should be thoroughly wiped dry and a 2 per cent silver nitrate solution applied to the membrane, particularly in the region of the orifice After the purulent stage has subsided and the discharge becomes mucoid, an astringent solution should be dropped into the ear after irrigation For this purpose, zinc sulphate, lead acetate or copper sulphate in 2 per cent aqueous solutions is very useful Here, again, the colloidal silver preparations are frequently used, but I have failed to see any beneficial results, and the staining of the tissues is often misleading to the eye The usual duration for discharge from the ear varies from a few days to four or six weeks, although in some cases it may keep up longer

COMPLICATIONS

In every case of middle ear infection, there is an involvement of the mastoid process This may be confined either to the mastoid antrum or diffused over the entire process It would be difficult to conceive of an infective process attacking the middle ear without extending by continuity of structure through the aditus ad antrum into the antrum Fortunately, the percentage of surgical involvement, i e, necrosis, is very small Two years ago, when the type of infection met was exceedingly virulent, of eighty cases of acute suppurative otitis media that came under my care during a period of two months, and which were seen from the onset and before spontaneous rupture of the membrane had occurred, but four required surgical treatment of the mastoid, so that I believe we can safely count on recovery in from 97 to 98 per cent of the cases without opening the mastoid, provided the patients receive the proper care from the beginning The mastoid tenderness that is almost always present during the early stage of acute suppurative otitis media can usually be promptly relieved by the application of cold, in the form of either a Leiter coil or an ice bag This treatment should be kept up continuously for from twenty-four to forty-eight hours If continued for a longer period it will accomplish nothing further but may mask other symptoms that might arise

When to operate and when to procrastinate are not always easy questions to decide Of course, when there is swelling, redness and tenderness over the process (the so-called classic symptoms of mastoiditis), indicating an erosion through the cortex, or when, with a profuse purulent discharge, there is a septic temperature after the first week that is not assignable to other conditions, then the indications for surgery are obvious The mastoids which do not present these symptoms, however, and yet demand surgical interference, are more usual than is ordinarily supposed It is not unusual to find an extradural or perisinus abscess at operation in a patient who has had neither tenderness nor rise of temperature, and who is apparently well except for the discharging ear Drooping or bulging of the superior and posterior wall of the bony canal adjacent to the tympanic membrane and the presence of discharge are sufficient indications for surgical intervention, regardless of the absence of other signs and symptoms The character and duration of the discharge must also be considered, as a persistent purulent otorrhea, which perhaps is not immediately dangerous to life, carries with it the possibility of becoming chronic and thereby destroying, to greater or less extent, the sense of hearing, and producing, at some future time, one of the dreaded intracranial complications If a case is at all doubtful, it is better to subject the child to post-auricular drainage, as we are fairly safe in counting on complete recovery in practically 100 per cent of the cases If the discharge is mucoid in character, without giving evidence of progressive destruction of the tympanic membrane, it can usually be cleared up (after the removal of adenoids and hypertrophied tonsils) by the administration of a mixed catarrhal vaccine I have had almost universal success with this line of treatment in this particular class of cases

The roentgen ray has become a strong factor in mastoid diagnosis When this work was first attempted, not much reliance could be placed on it, but with improved technic, and with careful comparison, by the roentgenologist and otologist, of the picture with the operative findings the value has been established, and many cases in which the findings are obscure can thus be correctly diagnosed The blood picture is of value when it shows a leukocytosis and increase in the polymorphonuclears, but should be ignored as a negative diagnostic point The explanation of this is easily found in the fact that the pus lies in a bony cavity from which there is little absorption until the lateral sinus or dura is exposed by erosion

Of the trinity of intracranial complications of suppurative middle ear disease, diffuse purulent meningitis is almost always fatal The majority of these cases can be prevented by a mastoid operation before such a condition arises There are, however, rapidly fulminating cases which nothing can stop, and in this class there is usually very little necrosis of the mastoid Brain abscess is a less common complication in the acute otorrhea, and here again prompt surgical intervention in a case of mastoiditis will usually prevent its appearance but when we do meet it, it is more amenable to treatment than meningitis Lateral sinus thrombosis is far more common in children than is generally supposed, and it is more difficult to diagnose in children than in adults The percentage of recoveries is fairly high if the condition is relieved by operation before other organs become involved or a general septicemia of a severe type manifests itself

CONCLUSIONS

1 Examination of the ear in children should be made routinely whether or not there are local evidences of involvement

2 The early recognition and proper treatment of acute suppurative otitis media will prevent the majority of cases of mastoid necrosis

3 Early surgical treatment of mastoid necrosis is the only means of preventing chronic otorrhea or the intracranial complications

Sixteenth and Spruce Streets

ABSTRACT OF DISCUSSION

DR WALTER E SIMMONDS Chicago I have found that there is danger in having any one other than the physician, or a nurse in whom I have the utmost confidence, irrigate the ear because the infection will spread in a tube which is more or less closed When there is moisture, try the dry treatment swabbing the ear with alcohol, and then instilling phenol

(carbolic acid) and glycerin It seems to work better Considerable experimental work has been done on the effect of draughts and cold on infected ears Dr J J Moore and I found that rabbits that were exposed to the electric light rays in a closed box under a proper regulated temperature controlled by a thermostat either did not develop lesions or had fewer or less severe lesions than those that were not so treated I found that children would readily get otitis media when exposed to drafts after colds or grippal infections I attended three families in succession in the same flat, which was cold and damp I had a child with acute otitis media and told the parents that I did not think we would get good results from treatment unless we removed the child to a hospital The child was taken to a hospital, and the first night the symptoms subsided the temperature went down and the pain disappeared After about ten days the child was returned to the flat and the next day there was a complete recurrence of pain and symptoms I apply heat to the part by using an electric bulb hot boric acid applications or a hot water bottle A hot salt bag is very useful Any one can apply the rays from an electric light bulb continuously to the region of the ear

DR OLIVER W HILL, Knoxville Tenn I would urge a routine examination of every child that comes under observation if it shows any sign of coryza or upper respiratory tract infection Many otologists are not certain as to when to interfere with an acutely infected ear and when to practice watchful waiting I should like to hear some one who has had experience explain how to determine, by the physical appearance of the ear, the type to interfere with and the type to let alone

DR HENRY DIETRICH, Los Angeles As to the time to interfere with ears, I do not believe that the physical appearance of the ear drum alone can determine that Another factor is that the virulence of the infection varies from year to year An ear which must be incised during one epidemic need not be incised during another During the epidemic two years ago, It was found advisable to incise almost every ear that showed any particular change and at that time complications on the part of the mastoid and sinuses were common This year our experience is quite different, that is, an ear drum which had the appearance of the ear drum of two years ago would heal under proper medical care

DR. CLIFFORD D SWEET, Oakland, Calif Too much emphasis cannot be placed on the routine examination of the child's ear It is important to impress on parents and general practitioners the importance of this as part of the general examination, and that there is no symptom on which you can depend to make the diagnosis I have seen the most virulent infection, with no sign from the child that would call attention to the ear One must be able to recognize the normal drum and also the appearance of the drum as the inflammatory process recedes or progresses With regard to the question as to whether to incise or to wait First, if there is any doubt, a skilfully done paracentesis can do no harm but it should be remembered that if the paracentesis is made too early before the process in the ear has progressed sufficiently, the incision will close up in from twenty-four to thirty-six hours only the upper part remaining open, and you will have to repeat the paracentesis Of course all of the clinical symptoms of the condition must be taken into consideration in deciding when to interfere and when not to interfere The question as to when to interfere in mastoid involvement requires more skilful team work than any other single point No ear discharges very long without involvement of the mastoid and I think that as soon as it can be definitely decided that the mastoid is involved, it should be interfered with surgically because of the serious consequences which may follow I was on the advisory board through which men passed in the draft, particularly from such communities as San Francisco Bay where the climate is damp and 4 per cent of the men were rejected because of chronic ear conditions We found that they had chronic ear disease which lighted up with colds It was apparent that these cases could have been cleared up by operations on the ear or tonsils and adenoids at the proper time

DR W MCKIM MARRIOTT St Louis I would like to draw attention to two points in the symptomatology of otitis media in infants One is that the otitis media may occur without any rise in temperature, even when there are definite signs of pus in the middle ear The only symptom noted may be a failure to gain in weight The second important symptom which may also occur, even in the absence of fever, is vomiting This symptom is often promptly relieved following paracentesis

DR S HERMAN LIPPITT, Milwaukee Something was said about the child's holding the hands to the ear or rolling the head from side to side in middle ear disease I have found those symptoms absolutely untrustworthy The only way to make a diagnosis is by the routine use of the electric otoscope I have found that following cases of tonsillitis and upper respiratory infections, many cases of otitis media developed one year and the next year, following the same types of infections, cases of pyelitis were numerous

DR A SPENCER KAUFMAN Philadelphia With regard to the indications for incision, there is one point to which I want to call attention, and that is, a retraction of the membrane with redness in an acute catarrhal otitis media is really a contraindication to incision, and when a membrane is incised too early, the slight hissing sound is caused by the air rushing into the vacuum that has been created by the sealing off of the tube I was glad to hear Dr Dietrich mention the varieties of infection one meets in different years This year it was not an uncommon thing to see a septic temperature (such as one would expect to find in a sinus thrombosis) accompanying a simple otitis media which cleared up without a surgical mastoid involvement The experience in examining the draft men very forcibly brings to our attention the necessity of the early care of these cases There is no excuse for a chronic discharging ear If the discharging persists, postauricular drainage will, in practically all cases, clear it up I think the class of cases that Dr Marriott referred to, the afebrile cases of otitis with discharge, usually comes during the period of dentition in infancy We all must recognize that infection of the middle ear comes too frequently during dentition to be a mere coincidence and very often the first symptom will be the evidence of discharge

---

SEQUELAE OF EPIDEMIC (LETHARGIC) ENCEPHALITIS*

WILLIAM HOUSE, M D
PORTLAND ORE

Recent literature on epidemic encephalitis has been so extensive that any addition may be a bore Nevertheless, such a probability is here risked in the hope of presenting a reasonably simple working classification of the sequelae of that disease H G Wells, writing of the education of the middle part of the last century, recently said, "The test of a good style was its abundance of quotations, allusions and stereotyped expressions" With all deference to the extensively reviewed writing and opinions of others, the practice that Wells scorns will be avoided on the ground that the literature is readily available and that time limits will permit of few excerpts These remarks are based on an examination of 145 patients with epidemic encephalitis, ninety of whom were examined during acute and fifty-five during chronic stages of the disease or because of sequelae Many of the patients were examined at remote distances and under circumstances that prevented detailed records Accordingly, an exact statistical study will not be attempted nor is it essential for present purposes Be it sufficient that no case was included that seemed diagnostically doubtful, but, conversely, that to the list might be added a considerable

*Read before the Section on Nervous and Mental Diseases at the Seventy Third Annual Session of the American Medical Association St Louis May 1922

number of cases insufficiently investigated which were probably due to epidemic encephalitis

Of the ninety acute cases, twenty-four are known to have been fatal, giving a known mortality of 26 per cent, with six or seven cases that may have terminated and probably did terminate fatally, so that it is quite likely that the total mortality was nearer 33 per cent The cases here discussed were taken from the remainder of these ninety cases plus the group of fifty-five cases seen during chronic stages or because of sequelae, which cases were themselves the residue of other groups whose mortality is unknown All of these cases occurred between late October, 1919, and January, 1922 The epidemic which furnished them moved in waves, the first lasting during October, November and December, 1919, with lesser waves in January and March, and complete subsidence by May, 1920 During this period, fifty-four acute cases were examined From October, 1920, to April 1921, there was an almost continuous series numbering thirty-six acute cases which were much less severe than those of the preceding winter, with a death rate little more than half as great

The succeeding remarks will be limited to the subject matter predicated by the title of the paper

COMPLETE RECOVERY

So many patients have been left with disagreeable sequelae that doubt has often been expressed as to whether any patient with epidemic encephalitis ever fully recovers Apparently many have been left little the worse as a result of this infection After deducting the fatal cases, probably one third of the patients are now well, though with rare exceptions convalescence was prolonged and he was indeed fortunate who, having suffered from encephalitis, was quite well at the end of a year, though many resumed work in from three to six months The remainder are still uncomfortable, many of them helpless, more in a condition of semi-invalidism which permits of some activities but robs life of much of its joy These unfortunates may be divided into four principal groups For descriptive purposes, the order of grouping is that of increasing ratio of interest rather than of numbers

FOUR GROUPS

Group 1 This group is least numerous, though not without interest, and is composed of those who in the acute stages exhibited myoclonus symptoms and who still suffer from muscular jerking and twitching, though in steadily decreasing severity There are but two pronounced cases in the nonfatal group, and in each, stabbing, lightning, neuritic pains characterized the early stages of the disease, and the patients still have considerable twitching but without pain They exhibit neurasthenic symptoms, have performed no continuous labor, and belong also in Group 3 They will not here be further discussed

Group 2 This is composed of those who exhibited definite psychoses The most common characteristics of these were suggestive of dementia praecox, with one paranoid case

Group 3 This is composed of those who showed symptoms suggestive of neurasthenia or psychoneurasthenia No attempt will here be offered to theorize on the pathologic reasons for the persistence of symptoms as between organic lesion, toxic condition, or pure psychopathy This is the largest of the four groups

Group 4 This group is composed of those who exhibited signs of gross organic lesion of the brain or cord It may be divided into three subgroups, the symptoms of which suggest

(*a*) A single unilateral brain lesion producing some such disorder as hemiparesis

(*b*) Lesions limited to the pons or medulla or both,, causing persistent oculomotor or bulbar disturbances

(*c*) Disseminated lesions, most classically revealed in the production of parkinsonian symptoms with many attendant and variable side effects

PSYCHOSES

Psychoses (Group 2) were, of course, present in a large number of the acute cases They persisted or developed as sequelae in not less than five cases, but had no pathognomonic characteristics The symptoms suggested that the patients were predisposed to mental disorders and that the psychoses were excited rather than caused by the infection Four of these patients were constitutional psychopathic inferiors, and in each the manifestations were typical of dementia praecox with plainly discernible hereditary elements

In one instance a child aged 6 years, had the daily habit of getting into a catatonic position late in the afternoon with his body curved forward his neck backward and his eyes directed upward as if toward some picture high in the air and maintaining this position continuously throughout the night until 7 or 8 o clock the next morning when he would go to sleep only to resume the strange position the following afternoon This he continued for about two months when he was first brought for study There was a definite history of encephalitis with double vision and other clinical concomitants four months preceding the psychosis, which was accompanied by partial speech inhibition, unwillingness to take food and other commonplace symptoms suggestive of catatonic dementia praecox The spinal fluid contained 8 cells per cubic millimeter with no other changes, and puncture was followed by temporary recovery with resumption of the catatonic position two months later Further track of him has been lost The mother of this child was a psychopathic inferior, and the father a nonentity

Three other cases of well defined dementia praecox type were noted, each following seemingly indisputable attacks of epidemic encephalitis In all of these cases there was good reason to believe that the psychosis was that of dementia praecox and that the encephalitis acted as an excitant of predisposed patients, just as war shock or other unusual experience acts on psychopathic personalities

The most disastrous psychosis occurred in a man, aged 59, who following a personally observed prolonged typical attack of epidemic encephalitis returned a year later At this time he suffered from typical paranoidal delusions of persecution with hallucinations of sight and hearing He believed that his wife was conspiring against him and that she was untrue to him He transferred his life insurance to other members of the family changed his will, made an unsuccessful attempt to kill his wife by shooting her and then committeed suicide Prior to his infection they had lived amicably but he had always been penurious in proportion to his wealth, peculiar in certain ways, and there was a strong suggestion that the encephalitis acted as an excitant rather than the entire cause of his psychosis

NEURASTHENIA AND PSYCHASTHENIA

The largest group (Group 3) was made up of those who became neurasthenic or psychasthenic or both The exact number so affected is not definitely ascertainable for, on the one hand, they departed from the normal so little and, on the other hand, shaded so gradually into the territory of the psychoses that it would be hard to say where neurasthenic and psychasthenic sequelae began or ended Almost constant sub-

normal blood pressure, anemia, vertigo, fatigability, deranged appetite, gaseous eructations, spinal weakness, tachycardia and palpitation, difficulty in mental concentration, poor memory, restlessness and insomnia (especially severe in two cases) form an unmistakable complex. Of interest in connection with the preceding double vision was the persistence of oculomotor asthenia, in some cases still present at the end of three and one-half years since the original infection. These patients uniformly complained of difficulty in reading, typified in the statement of one of them made three years after infection, who said 'I can use my eyes very well, but they do not want to work.' With ordinary test cards his vision was good, there was no difficulty in distinguishing words or letters but after reading a short time he wanted to quit, the type blurred, his eyes were fatigued, his mind would not concentrate and he soon gave up reading as an unpleasant and laborious task. Though previously a capable electrician, he is still unable to work except part time and on small, unimportant jobs. Most of the patients with this oculomotor fatigue dislike moving pictures, bright lights, undue exposure to light, and any labor which involves prolonged and concentrated thought or action. In a word, they are typical psychoneurasthenics with predominance of oculomotor symptoms. It is hard to escape the conviction that some of them were neurasthenics in advance of the affection. In fact, with several of the worst cases this is known to have been the case. In varying degree these neurasthenic symptoms remain in a large percentage of the entire group which forms the basis of this discussion. Many belonging to Group 3 should recover.

Fundus examination in many cases suggests certain changes which, owing to apologetically acknowledged lack of real expertness with the ophthalmoscope, may be imperfectly described, consisting of slight blurring and indistinctness of the outlines of the disks and of the retinal blood vessels, both veins and arteries. There was no case of true papillitis or papilledema or optic nerve atrophy, and such changes as persist are comparatively slight and might escape notice were one not looking for them. Pupillary inequalities and sluggish reactions, especially in the parkinsonian cases were common, and in at least three cases rigid pinpoint (Argyll Robertson?) pupils were noted.

ORGANIC LESIONS

Hemiparesis.—Two patients remain hemiparetic. One was distinctly hemiplegic for six months after which his gait and faulty hand position slowly improved. The leg is still slightly rigid, and the forearm and hand seek a somewhat flexed position across the lower part of the abdomen in a manner suggestive of hemiplegia. The minds of both these patients have lost their flexibility, and they meet with difficulty in creating new thoughts or new ideas, though both pursue their businesses reasonably well but without the vigor and enthusiasm of bygone days.

Pontile Symptoms.—Several patients still exhibit weakness of one or more ocular muscles accompanied by slight strabismus which they are able to overcome temporarily by an effort. One man has a rather complete ophthalmoplegia, with marked limitation of motion of the eyeball in all directions. A woman, one year after an attack of fever accompanied by double vision from which she recovered, suddenly without warning developed inability to raise her eyeballs above the horizontal level, that is, she has paresis of both superior rectus muscles. There is some ptosis, and her habitual attitude is one in which the eyeballs turn down as if she was reading a book in her lap. All of the patients with oculomotor palsies excepting the last one belong to the parkinsonian group, but this one has no other symptoms suggestive of that disorder. These oculomotor symptoms seem clearly to point to a chronic poliencephalitis superior.

Bulbar Symptoms.—Those who present sequelae suggesting lesions of the medulla were relatively few, probably because lesions of the medulla were usually fatal, except as medullary symptoms were present in certain of the parkinsonian cases. Three patients with typical parkinsonian symptoms periodically find difficulty in swallowing, and suffer from excessive salivary secretion and constant trembling about the lips and tongue which suggest incipient bulbar paralysis. Since there has been a steady advance in the symptoms of these over many months, there is justification for the fear that they will eventually die from involvement of the bulb.

Parkinsonian Cases.—Twelve patients with a marked parkinsonian syndrome remain, 10 per cent of the nonfatal group. At least four of the fatal cases were of the parkinsonian type, so that the total number of cases of this complex was approximately 11 per cent. In addition, some of those classified as neurasthenics showed slight blankness of expression, rigidity of movement and other mild parkinsonian symptoms, which have gradually diminished. The parkinsonian disorder was characterized by the early development of loss of expression, staring, unwinking eyes, muscle rigidity and gait difficulties, all of a type similar to the second stages of paralysis agitans but without the characteristic tremor. Three patients suffer from excessive and annoying salivary secretion. In addition to the more or less characteristic rigidities there was, on occasion, a tendency to the assumption of strange and unusual positions, in a sense not dissimilar from that already described in the child who appeared to suffer from catatonic dementia praecox. A man, aged 23, who is excessively rigid, has lain for many months face downward on a couch with his hands drawn forward under him in characteristic parkinsonian fashion. When erect, he finds difficulty in turning his body, moves slowly, and walks with a rigid gait. When left alone he resumes the prone position. His mind acts slowly but clearly, and his speech is hesitating.

It was early noticed that these patients lacked the characteristic tremor of agitans. Some tremor has been present in most of the cases, but with one exception has never been constant. It has sometimes appeared in one hand or one leg, sometimes has been under control and sometimes has suggested the intention type, but, in the main, when patients were under observation it has been absent, that is, controlled. An exceptional tremor occurred in a patient already described as suffering from ophthalmoplegia. This man suffers from continuous tremor involving his entire body, including his vocal cords, so that his voice has a bleating sound. The tremor lacks the characteristic pill rolling motion, and is much more rapid than agitans.

Parkinsonian symptoms appeared in patients from 21 to 65 years of age. In only one of this group were the characteristics typical of paralysis agitans. This was in a man, aged 65, who gave a clear-cut history of onset

with double vision, fever and lethargy, but was unable to tell when he first began to shake It seems reasonable to suspect that here was a patient with incipient paralysis agitans who also had the misfortune to contract epidemic encephalitis

A final curious result of complication of the parkinsonian sequelae occurred in a woman, aged 48, who now, nearly three years after the date of infection with typical epidemic encephalitis, is expressionless, rigid in gait, and has a blood picture of pernicious anemia

COMBINED AND ATYPICAL SEQUELAE

Though an attempt has been made to separate the different types of sequelae of epidemic encephalitis, it has not been easy to classify every patient, for the reason that some patients could be classified in two or even three groups Some of the neurasthenic patients had partial ophthalmoplegic disturbances A violently agitated patient, twice discussed suffered from parkinsonian syndrome, ophthalmoplegia and pronounced psychosis and muscular jerking, in fact, he might have been classified in any of the groups

Occasionally, patients have complained of atypical sequelae, such as neuritic pains which were not of sufficient frequency or distinctness to warrant separate classification No postencephalitic convulsions occurred There was apparently complete absence of visceral lesions as distinct sequelae, though in two cases, after the acute onset of the disease, glycosuria of marked degree was observed, and it is possible that search over the entire group might reveal other cases showing visceral lesions It is probable that in both these cases the glycosuria was due to irritation of the fourth ventricle, but it is not unreasonable to assume that, if long continued, such irritation might result in permanent changes in the glycogen-forming organs

ABSTRACT OF DISCUSSION

DR M A BLISS, St Louis Among the sequels of epidemic encephalitis as observed in St Louis the most striking thing we noted was the great similarity to the remissions and exacerbations of multiple sclerosis We have patients who improve so markedly that we think they are well on toward recovery, and then the symptoms recur That has happened in our experience many times

DR F E COULTER, Omaha We are very frequently asked Will these patients recover? How long are they going to be ill? Are they going to be as well as before they were attacked with this disease? Sufficient time has probably not yet elapsed to answer those questions accurately I was glad to hear the optimistic views expressed by Dr House My own experience has not been quite so optimistic, especially with those persons who have had this disease in early life I wish he would tell us concerning these results in children The cases in children seem to have resulted in the most havoc, for the greatest destruction to the mental and nervous apparatus is found in the children The longer the duration the more severe the condition has been, also, the longer the period of lethargy, the more serious has been the result so far as sequels are concerned, especially in connection with children

DR WALTER L TIMME, New York I believe that the death rate is not nearly so high as Dr House represents his to have been I think the reason for the high death rate reported by him is that a great many persons with the disease in a very mild form seldom come under the observation of the specialist or go to the hospital These cases are seen by no one at all, or by a family practitioner, who sees the patient for a day or two in a mild febrile state prescribes some therapeutic treatment and the patient recovers I am convinced that a great many cases of this kind escape us entirely, and hence our mortality statistics must be taken with that reservation Dr House mentioned the Argyll Robertson pupil I have never seen in these cases a true Argyll Robertson pupil It is a pupil which reacts perhaps not at all to light, or possibly very sluggishly, but is also accompanied by an accommodation spasm so that we have a definitely fixed pupil rather than one that reacts to light and not to accommodation Occasionally we see a case that shows the marked effect of the infection on the vegetative nervous system and the related organs In a certain number of cases these patients become very adipose as a result of the attack an increase in weight of 60 or 80 pounds in the course of six months being not at all uncommon Another type of case seen only seldom is one in which there is a bronzing of the entire body within four or six months after the attack of encephalitis The intense asthenia seen in true Addison's disease is also present

DR GEORGE A MOLEEN, Denver I do not think any disease has been fraught with so many difficulties particularly directed to the neurologist as epidemic encephalitis I am frank to confess that that has been my experience, and I have derived a great deal of consolation from the fact that both the French and the German journals are replete with instances of the same kind The widest divergence in syndromes is evident in these reports, in conformity with my own experience I was interested in the classification brought out by Walsh, in which he segregated the cases into two groups in accordance with the positive and negative classification of other conditions by Hughlings Jackson By the positive cases he referred to those which had active muscular contractions with the active mental symptoms the nystagmus and the irritative sensory disturbances, particularly pain The negative types included the anesthesias and paralyses with the associated atrophies the somnolence and lethargy and the pupillary or eye paralyses with them He stated that the prognosis was universally better in the paralytic types than in those which showed the muscular or mental activities, and that has been my experience Also in the active motor types the sequels are more likely to occur At the New Orleans session I related a case which had not terminated at that time The patient was admitted with a bulbar paralysis the inability to swallow, and paralysis of the tongue Atrophy of the tongue with sagging of the palatine pillars was followed by paralysis of the shoulder girdle and a poliomyelitic type paralysis of the lower extremities Recovery occurred in the same order and I remember mentioning that his ability to swallow recurred with the presentation of a dish of strawberries The man went on to complete recovery and not a single evidence of his condition remains This is only one case in conformity with Walsh's contention

DR W A JONES Minneapolis We see so many cases that resemble encephalitis that I think for a time we were inclined to diagnose almost every neuropsychiatric condition as encephalitis I distinctly regret that in one case I emphatically decided that a woman who had a few psychiatric symptoms had an encephalitis She was sent to the hospital, and within twenty-four hours developed a stuporous state that resembled the stupor of a lethargic encephalitis she wakened for her meals and was conscious of the activities of the nurse A puncture of the spinal canal revealed that she had a four plus Wassermann reaction Her stupor became intensified and she died in a week The necropsy revealed nothing in the way of an encephalitis Aside from her Wassermann reaction she had a large intraventricular tumor of the brain Previous to seeing this case I had a similar case in which there was the same attitude of somnolence without symptoms of encephalitis, and, singularly, the woman had a large brain tumor With this confusion of symptoms in the cases that we see now we should be reasonably careful in coming to a definite conclusion

DR LEO M CRAFTS Minneapolis One thing that has impressed me is the uncertain chronicity of this condition I do not think that we yet know how long the process may continue either directly or its sequels I have in mind a case of encephalitis in which there was a quite typical attack with paralysis of the left face and arm, with lethargy The patient apparently made a fair recovery but was not in really good condition The following winter he presented

the same clinical picture again and died I am now observing a young ex-service man who had an attack of influenza in the fall of 1918 and was never well afterward More than a year later he developed the active picture of epidemic encephalitis He gradually improved but has continued to show the parkinsonian picture since that time, without tremor, but with the boardlike expression and automatic movement He is now steadily retrograding I believe that he has a continued encephalitis, either a chronic process without the activity of a germ or with it The cases that have impressed me most have been those that resembled brain tumor In one case the condition began as a simple nervous prostration but gradually retrograded The patient continually spat, an unusual symptom Later he developed an active cephalalgia that did not yield at all to treatment He lost motion on the left side which symptom disappeared He developed double choked disk but this definitely receded after spinal puncture and one drainage, and did not recur In the light of experience with this case I think that this fact, together with the rapid qualitative change in the reflexes from normal to abnormal and back, are the best differential points between actual brain tumor and encephalitis In the case referred to, resembling brain tumor with cerebellar nystagmus and falling backward, a double decompression was done at the occipital level Microscopic examination of the brain revealed some of the characteristic signs of cell infiltration about the blood vessels, but nothing else I have seen one case simulating spinal cord tumor, beginning with a definite zone of pain in the lower back and only after several months developing delirium diplopia and the ordinary progress One of the many striking things is the almost unfailing marked elevation of temperature toward dissolution, usually going to 106 F or above

DR JULIUS GRINKER Chicago The question of tumor that may be diagnosed when there is an encephalitis, and, on the other hand, the diagnosis of encephalitis when there is a tumor, was strikingly brought out by a case of encephalitis with choked disk A colleague had a case with choked disk which he presented as a case of encephalitis, characterizing it as the second case of encephalitis with choked disk mine being the first—choked disk being a very unusual symptom of epidemic encephalitis My colleague's patient died and the condition proved to be a true tumor of the brain My patient exhibited choked disk and also showed symptoms which Dr Crafts referred to and form which he would have made a diagnosis of tumor, but the patient made a perfect recovery His was a true case of encephalitis This goes to show that we are likely to mistake organic disease of other types for encephalitis and vice versa An interesting point is this Recently I saw a number of sequels of encephalitis in cases which were never diagnosed as encephalitis at all These sequels were mostly in the form of postencephalitic rigidity and parkinsonian tremors I have seen many cases which exhibited this syndrome These cases occur with preference in young persons A young boy had what was undoubtedly an encephalitis lasting for six months, during which he was apathetic drowsy and in bed most of the time—the case was not diagnosed as encephalitis The condition began with ocular phenomena, a little fever and undoubtedly must have been encephalitis though I had no opportunity of seeing the case myself at that time This boy now presents the following complications, which some one called a genuine sequel of encephalitis Every alternate morning sometimes every morning the boy, after awaking would run about the room in a frenzy swear at his mother and jump at her Aside from these attacks, he was a very well behaved child This sequel was directly attributed to the encephalitis The diagnosis appeared doubtful to me The mother described his attacks as being accompanied by blanching at the lips with change in color of the face and the suggestion arose May this not be a form of epilepsy? I gave him phenobarbital (luminal) and he did not improve Finally after studying the case I found that at times he did not swear, especially when something harsh was said to him I then advised the mother to spank the boy every time he had an attack and he has not had any more The case was evidently a neurosis of the hysteria group

DR CHARLES R BALL, St Paul I remember the first time I saw one of those parkinsonian types of encephalitis It was at Base Hospital 9, at Chateroux in 1918 I was called in consultation to see a young soldier who was sitting up in bed with a perfectly masklike expression on his face, and a marked degree of muscular rigidity I was told that he had recently had a rather severe attack of influenza in which he had been delirious for a number of days I recognized immediately that here was something new in my experience, something entirely different than I had ever seen before A few weeks later at Base Hospital 214 at Savaney at one of our weekly clinical conferences, we were able to show seven cases of this type of encephalitis The literature has since been filled with a protean symptomatology of the various types of this disease which present definite somatic findings At present because of this extensive literature on this subject, when there are somatic symptoms the recognition of the nervous sequelae of this disease is not difficult But what about the other sequels, when there are no objective symptoms when the history of the attack is vague, and when we have to deal simply with changes in the personality, or with symptoms entirely referable to the vegetative nervous system? We are called on in such cases to explain strange and unfamiliar nervous and mental conditions which we have previously classified under hysteria and psychoneuroses We see undoubtedly many such cases among ex-service men, that at present because of our lack of understanding of these sequels we are classifying as shell shock It is in this type of postencephalitic sequel that our most difficult problems in nervous diagnosis are to be found at present

DR J C MICHAEL Minneapolis A case which interested me very much was that of a young man who had delirium for about three weeks He became quite markedly parkinsonian for a year and a half Then he suddenly developed acute symptoms again and died At necropsy the usual pathologic changes of epidemic encephalitis were presented

DR FRANK A ELY, Des Moines I wish to report one case treated by thyroid A girl, aged 17, became ill one year before I saw her She was a pitiable object unable to continue her work in high school a typical parkinsonian end-result As an empiric treatment I asked her physician to give her from 3 to 5 minims of 1 1 000 epinephrin solution hypodermically every other day and to administer small doses of thyroid beginning with 1 gram a day and increasing the dose to 5 grains Within sixty days this girl had regained her usual alert state her mentality improved she was able to go about and resume her studies, and recently, about six months after institution of the treatment, I received a report that she was apparently perfectly well I realize that one case means nothing it is simply a report for the sake of stimulating observations along that line I have had one other typical parkinsonian case in a service man who had peculiar respiratory phenomena in which he snorted all the time a peculiar forcible exhalation He was very much improved as long as we kept him on the thyroid and epinephrin As soon as the treatment was discontinued, his respiratory difficulty would return

DR. WILLIAM HOUSE, Portland Ore Dr Bliss refers to multiple sclerosis cases Dr Bassoe first called attention to the hope that in encephalitis we might find the etiology of paralysis agitans and multiple sclerosis I think that his hope has not been fulfilled The results of encephalitis do not appear to be typical of agitans or multiple sclerosis Dr Coulter speaks of my optimism in prognosis I pointed out the difference that existed in opinions, and think my prognoses not too optimistic I believe that the last group that I presented Group 4 will have no recoveries but that the neurasthenic and myoclonus cases will recover I saw very few children Most of the cases of encephalitis in children that I saw were fatal Answering Dr Timme's comment on the high death rate six of my first thirteen cases were fatal, but as the epidemic advanced the cases seemed less virulent in this respect corresponding to experiences with poliomyelitis in which the first epidemic was always much more severe than the recurrences of the following winter In the second series of cases of encephalitis there were many of the mild type described by Dr Timme patients with a temperature of about 101 or 102 F some delirium and a few days of double vision followed by lethargy and recovery In regard to the Argyll Robertson pupil I think that Dr Timme made a just

correction These pupils are not Argyll Robertson, they are simply contracted pupils in which responses to both light and distance are greatly diminished Dr Moleen speaks of nystagmus It seems to me that there is no true nystagmus in these cases The wavering motions that exist are due to muscle weakness and are a pseudonystagmus and not a true one As to prognosis in paralytic cases Mine were severe cases The patients have not done well, and all of them have some sequel Of the myoclonus patients, some have died and others have severe mental and physical sequels, except the two mentioned In regard to the difficulties in diagnosis I found some trouble in differentiating between brain tumor and encephalitis especially tuberculous meningitis and encephalitis In most cases it should be fairly easy to make an accurate diagnosis A final suggestion in connection with the association between encephalitis and various psychoses may be of interest Most of my patients were in poor health when they developed encephalitis They were subnormal, and, in view of my belief that the psychotic cases occurred in psychopaths, it seems to me that subnormal persons are more predisposed to the disease than normal persons

Clinical Notes, Suggestions, and New Instruments

DEAFNESS FROM PRESENCE OF INSECT IN EAR

PAUL A HICBEE M D MINNEAPOLIS

A man, aged 36 stumbled and fell, Feb 18, 1922, striking on his chin He was unconscious for a few seconds and, on recovering, experienced a sharp pain in his right ear After the chin wound was dressed he was referred to me for examination of the ear The external canal was blocked A large amount of debris was removed, disclosing tightly packed cerumen, which was removed with difficulty Following this came the remains of a dead cockroach, 18 mm in length and perfectly preserved in every detail

The patient in April, 1908, while preparing for a bath, felt a sudden pain and buzzing in the right ear, which drove him almost frantic While his wife was telephoning for a physician, he put his head under the water in the tub, and the pain soon ceased Later on the advice of his physician, the ear was syringed, but nothing was washed out of the ear, and it was supposed that the trouble was due to a small mite which had been lost in the washing The patient gradually became deaf in this ear, but never consulted a physician, believing that some irreparable damage had been done to the ear by the insect After removal of the insect and cleansing of the canal, hearing was fully normal, and the only evidence of injury was a slight abrasion of the drum

It seems probable that, following the original injury in 1908, the canal became gradually filled with wax, thus entombing the insect in an air-tight space and preserving it in toto for nearly fourteen years

MODIFIED EINHORN THREAD TEST

EDWARD STEINFIELD M D PHILADELPHIA

The equivocal results in the use of Einhorn's thread test in the diagnosis of gastric ulcer and malignancy have been due in part to the difficulty in the recognition of the stains as blood Though other objections have been advanced from time to time by various observers, it has appeared that modifications tending to render the test more sensitive would be of material aid in increasing the usefulness of the procedure The outlining, by chemical methods, of the areas on the thread impregnated with blood, renders the identification of faint or doubtful blood stains less difficult A method utilizing this principle has been used recently, and the results are sufficiently encouraging to warrant its trial as a source of added information in suspected lesions of the stomach and duodenum The entire procedure is as follows

The patient abstains from meat on the day the test is done, or for a longer preceding interval if symptoms of pyloric obstruction are present A "pearl" button (from 7 to 8 mm in its greatest width) attached to a thread of braided silk is swallowed by the patient at 9 p m and washed down by a glass or two of water A knot at 75 cm marks the limit to which the thread is allowed to travel The next morning a mark is made at the part in contact with the teeth, and the thread and button are removed before any food has been given Successive strips of 10 cm each, starting from the external dental mark, are tested in a small porcelain dish with the benzidin and hydrogen peroxid mixture which is commonly used for occult blood tests Stains due to blood assume a green color, and the proximal stain counting from the mouth end, may be taken as the probable distance of a bleeding area However, it is not advisable to regard the calculation of this possible site as being positively established A sensitive benzidin is of value, and a hydrogen peroxid solution not containing acetanilid is preferable It is possible to make a preliminary trial, using a two or three hour interval only, in some cases this is sufficient to give enough blood impregnation to react definitely In case of doubt, however the longer time given above is the method of choice Oxidations of the benzidin due to the presence of oxydases have not been noted in this technic

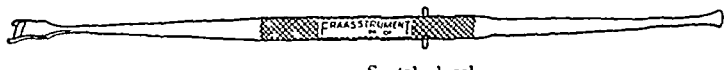
A NEW SEPTAL CHISEL*

CREIGHTON BARKER M D NEW HAVEN CONN

This instrument is designed for the removal of the base of the nasal septum and septal ridges It has been used by a number of rhinologists with gratifying results Essentially, the instrument is a Freer chisel to which tiny rounded knobs have been added to protect the sharp corners of the blade The advantage of this protection are clear—it is practically impossible to injure with it the overlying mucous membrane The projections at the sides of the blades also make it easier



Septal chisel

to hold the cutting edge against a narrow projection without slipping, and its use with the blade vertical, as in severing a spur, is facilitated thereby

66 Trumbull Street

A FILTERING ADAPTER FOR THE ADMINISTRATION OF NEO ARSPHENAMIN

JAY F SCHAMBERG M D PHILADELPHIA

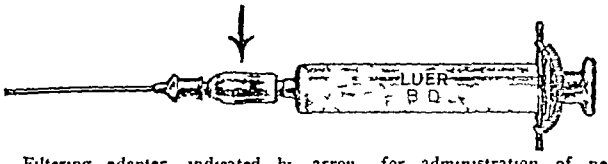
During the World War, the practice became common abroad of administering neo-arsphenamin in concentrated solutions in a small Luer syringe This practice has likewise been adopted by many physicians in this country It possesses the advantage of simplicity of administration and of time economy, factors which are important when large numbers of patients in clinics are treated

When concentrated solutions are used with a Luer syringe, and even when larger quantities of water are employed, it is quite possible for minute fragments of glass dust, dust in the water or undissolved particles of the drug to be carried through the needle Such particles, while not large enough to be readily visible to the eye, may still be of sufficient size to cause an embolism in the minute capillaries of the lungs or possibly other organs It is probable that the nitritoid and similar immediate reactions which follow the administrations of arsphenamin are due to embolic processes It is now common knowledge that solutions of neo-arsphenamin

* From the Ear Nose and Throat Service Grace Hospital

which are turbid or cloudy will produce immediate symptoms, characterized often by flushing followed by weakness and sometimes collapse It is known that acid solutions of arsphenamin produce emboli in the vessels of the lungs, a fact which may be definitely demonstrated in experimental animals The monosodium salt of arsphenamin injected in the strength of 0 4 gm in 20 c c of water has been followed by the development of embolic bronchopneumonia The use of the disodium salt which is produced by neutralizing with excess of alkali, appears to lessen the liability of embolism by reason of the fact that the blood serum is less likely to be precipitated in the presence of the increased amount of alkali These considerations lend some support to the thought that occasional nitritoid and immediate reactions after injections of neo arsphenamin may be due to the presence of unsuspected small particles of the character described, which might be readily removed by filtration

While some physicians filter solutions of neo-arsphenamin the practice is generally not carried out If it could be performed without any undue exposure of the neo-arsphenamin to contact with air and increased liability to oxidation, it would be an advantage The filtering adapter which has been made up for us by the Becton-Dickinson Company gives us an opportunity to secure filtration without increased exposure to air The adapter consists of a small glass tip about 30 mm in length which snugly fits the tip of the syringe Inside the lumen is placed a small pledget of absorbent cotton When the solution of neo-arsphenamin is poured into the barrel of the syringe, it is readily filtered by



Filtering adapter indicated by arrow for administration of neo arsphenamin

passing through this pledget of cotton After filtering in this way, if one removes the pledget of cotton and examines it with strong magnifying lenses, one may often note the presence of minute particles of solid material representing particulate matter of one kind or another which would otherwise have gone through the syringe from the needle into the vein One may readily insert the cotton and sterilize the tip in a sterilizer at the same time that the syringe is rendered sterile The filtering adapter likewise answers the purpose of a safety device, insuring the presence of the needle in the vein when injecting dark solutions of any kind for the solution remains in the syringe and the blood may be seen mounting through the filtering adapter

New and Nonofficial Remedies

THE FOLLOWING ADDITIONAL ARTICLES HAVE BEEN ACCEPTED AS CONFORMING TO THE RULES OF THE COUNCIL ON PHARMACY AND CHEMISTRY OF THE AMERICAN MEDICAL ASSOCIATION FOR ADMISSION TO NEW AND NONOFFICIAL REMEDIES A COPY OF THE RULES ON WHICH THE COUNCIL BASES ITS ACTION WILL BE SENT ON APPLICATION W A PUCKNER SECRETARY

EPINEPHRINE (See New and Nonofficial Remedies, 1922 p 108)

Epinephrin-G W C Co—A brand of epinephrine-N N R

Manufactured by the G W Carnrick Co New York No U S patent or trademark

Epinephrin G W C Co Vials containing epinephrin G W C Co (base) 1 grain

Epinephrin Chloride Solution G W C Co A solution containing epinephrine hydrochloride equivalent to 1 part of epinephrine in 1 000 parts of physiologic solution of sodium chloride and preserved with hydrochloric acid (equivalent to HCl, 0 02 per cent)

PITUITARY EXTRACT-LEDERLE (OBSTETRICAL)—An extract of the posterior lobe of the pituitary body of cattle approximately two and one-half times the strength of solution of hypophysis, U S P, preserved by the addition of chlorbutanol, 0 5 per cent It is standardized according to the method of G B Roth as modified by R. A Spaeth (Bull 115, U S Hygienic Laboratory)

Actions and Uses—See general article Pituitary Gland (New and Nonofficial Remedies, 1922, p 213)

Dosage—From 0 5 to 1 0 Cc (7 to 15 minims)

Lederle Antitoxin Laboratories New York No U S patent or trade mark

Ampules Pituitary Extract Lederle (Obstetrical) 0 5 Cc
Ampules Pituitary Extract Lederle (Obstetrical) 1 Cc

PITUITARY EXTRACT-LEDERLE (SURGICAL)—An extract of the posterior lobe of the pituitary body of cattle approximately five times the strength of solution of hypophysis U S P preserved by the addition of chorbutanol 0 5 per cent It is standardized by the method of G B Roth, as modified by R A Spaeth (Bull 115, U S Hygienic Laboratory)

Actions and Uses—See general article Pituitary Gland (New and Nonofficial Remedies 1922, p 213)

Dosage—Usually 1 Cc (15 minims)

Lederle Antitoxin Laboratories New York No U S patent or trade mark

Pituitary Extract Lederle (Surgical) 5 Cc vial

TYPHOID VACCINE (See New and Nonofficial Remedies 1922 p 310)

Parke Davis & Company Detroit

Typhoid Vaccine (Prophylactic)—Marketed in packages of three ampules (*Bio 427*) one containing 500 million and two 1 000 million killed bacteria each also in packages of three syringes (*Bio 426*) one containing 500 million and two 1 000 million killed bacteria each

GONOCOCCUS VACCINE (See New and Nonofficial Remedies, 1922 p 301)

Parke Davis & Company, Detroit

Gonococcus Vaccine—Marketed in packages of four 1 cubic centimeter bulbs (*Bio 271*) each containing 1 000 million killed bacteria in packages of four 1 cubic centimeter syringes (*Bio 273*) each containing 1 000 million killed bacteria also in 5 cubic centimeter (*Bio 274*) and 20 cubic centimeter (*Bio 275*) bulbs containing 1 000 million killed bacteria per cubic centimeter

STAPHYLOCOCCUS VACCINE (See New and Nonofficial Remedies 1922 p 306)

Parke Davis & Company Detroit

Furunculosis Vaccine—Marketed in packages of four 1 cubic centimeter bulbs (*Bio 255*) each containing 2 000 million killed *Staphylococcus aureus* obtained from furuncular lesions in four 1 cubic centimeter syringes (*Bio 257*) each containing 2 000 million killed staphylococci also in 5 cubic centimeter (*Bio 258*) and 20 cubic centimeter (*Bio 259*) bulbs each containing 2 000 million killed staphylococci per cubic centimeter

Staphylococcus Vaccine (Combined)—Marketed in packages of four 1 cubic centimeter bulbs (*Bio 376*) each containing 1 000 million killed *Staphylococcus albus* and 1 000 million killed *Staphylococcus aureus* in four 1 cubic centimeter syringes (*Bio 378*) each containing 1 000 million killed *Staphylococcus albus* and 1 000 million killed *Staphylococcus aureus* also in 5 cubic centimeter (*Bio 390*) and 20 cubic centimeter (*Bio 391*) bulbs each containing 1 000 million killed *Staphylococcus albus* and 1 000 million killed *Staphylococcus aureus* per cubic centimeter

VACCINE VIRUS (See New and Nonofficial Remedies, 1922 p 290)

Parke Davis & Company, Detroit

Vaccine Virus—Marketed in packages containing one capillary tube (*Bio 560*) for one vaccination with a rubber bulb for ejecting the vaccine and a needle for scarifying and in packages containing five capillary tubes (*Bio 561*) for five vaccinations with a rubber bulb for ejecting the vaccine and a needle for scarifying

ERYSIPELAS AND PRODIGIOSUS TOXINS (COLEY) (See New and Nonofficial Remedies 1922, p 316)

Parke Davis & Company Detroit

Erysipelas and Prodigiosus Toxins (Coley)—Marketed in packages containing five 1 cubic centimeter bulbs (*Bio 451*) and in 10 cubic centimeter bulbs (*Bio 455*)

First Practical Clinical Instruction—Prof C Fedeli of Pisa has found records which establish that an Italian physician named Da Monte opened at Padua in 1543 in the Franciscan Hospital a school for practical instruction in clinical medicine This, he says was the pioneer institution of the kind Boerhaave founded a similar one in Leiden in 1714 and Van Swieten at Vienna in 1745 Then came Prague 1781, Gottingen 1786, Jena, with Hufeland 1793, Edinburgh, 1741 Oxford, 1780 and Paris 1795

PURER FOODS AND DRUGS

Great reforms are seldom accomplished over night They are usually the outcome of a slow but unfailing evolution due to prolonged educational effort, sometimes coupled with the vigorous enforcement of new measures By reason of the gradual appearance of the changes brought about, evidence of actual reforms is often difficult to secure when it is sought at too frequent intervals This is likely to lead to discouragement at times, unless the searcher takes occasion to let longer periods of efforts at improvement pass in review so that the total accomplishment can more readily be envisaged

The foregoing comments apply in large measure to the history of the attempts to improve the situation with respect to the marketing of foods and drugs In this country the cumulative effect of national and state legislation, together with the propaganda of various agencies and the police powers exerted by the proper authorities, has not failed to manifest itself in the last decade The Food and Drugs Act, the 'net-weight package laws, and the now numerous local enactments directed to secure similar benefits have left their imprint in a better situation Nevertheless, in the counsel of perfection the doctrine of eternal vigilance still finds a place This is illustrated in the latest report of the chemical laboratory of the Connecticut Agricultural Experiment Station at New Haven,[1] to which reference has often been made in relation to pioneer work in the detection of adulteration and fraud in American food and drug products Thanks in considerable measure to the persistent effort of such laboratories, together with the Council on Pharmacy and Chemistry of the American Medical Association so-called diabetic foods especially recommended for a class of patients including, in this country alone, a million persons peculiarly susceptible to improprieties of diet no longer continue to be offered for sale in so many instances with utter disregard of the content of carbohydrates, which are supposed to be greatly reduced for the benefit of the sufferers Only a few years ago there were extremely few "honest" diabetic foods Today the number of reputable products with truthful claims is largely increased Yet Bailey's report[1] shows the sale of a "starchless breakfast food" containing more than 64 per cent of starch, not to mention the additional sugar content There are "glutenized" cereal products containing 50 per cent of starch and soluble sugars, yet recommended for diabetic patients Gluten products containing more than 65 per cent of available carbohydrate, and therefore no more suitable than ordinary wheat bread for the diabetic, are advertised still, but they have lost their former prominence in the face of an educated medical profession and a cautioned purchasing public

It is encouraging to note that out of nearly four hundred specimens of U S Pharmacopeia drugs examined by the Connecticut Station in 1921, only sixty-two were found adulterated, below standard or otherwise illegal Most frequently, derelictions were found in the case of bay rum, essence of peppermint and similar products, which have no great significance in therapy Even solution of calcium hydroxid, which so often has left the druggist's shelf as moderately pure water, having parted company with its content of lime during a prolonged sojourn there, is found to be up to standard with reasonable frequency

The situation is not ideal, by any means, but the curve of progress is showing an upward tendency

ANHYDREMIA AND FEVER

The part played by water in the regulation of bodily heat and the equalization of temperature in the living organism is not as well appreciated as it deserves to be L J Henderson[1] has pointed out that water ranks high with respect to three qualities specific heat, heat of evaporation, and conductivity The first favors the storage of heat, the second permits of very rapid elimination when necessary, as when environmental temperature exceeds that of the body, the third allows rapid equalization of heat within the fixed tissues of the body, minimizing the possibility of injury from local overheating within or without

In this country, both Woodyatt and Barbour[2] have emphasized the part which the distribution of water in the body plays in relation to the phenomena of fever, which has been defined as "any condition of positive heat balance not due solely to food, exercise or environment" An increasing number of investigations in recent years are beginning to demonstrate that noticeable alterations in the water content, that is, the concentration of the blood, occur where they were formerly not suspected The untoward effects of

1 Henderson L J The Fitness of the Environment 1913

2 A review of the subject is given by Barbour H G The Heat Regulating Mechanism of the Body Physiol Rev 1 295 (April) 1921

such "anhydremia" have already been referred to in THE JOURNAL [3] Balcar, Sansum and Woodyatt [4] have demonstrated in a striking way how intravenous injections of strong glucose solutions may lead to high temperatures, which they attribute to the concentration of the blood, and the lack of water for giving off heat Anhydremia in children is attended with serious febrile symptoms, which Marriott [5] has clearly described In influenza, loss of fluid from the blood prognosticates a temperature rise and a change for the worse, which may often be averted by intravenous administration of fluids [6]

Facts seem to be accumulating rapidly to help establish these newer views on a firm experimental basis Water constitutes more than 70 per cent of protoplasm, the structural basis of organic life [7] Various drugs seem to modify the water balance, or at least the distribution of water in the body, and thereby affect the regulation of body temperature A new instance has been described lately by Barbour and Moise [8] in the case of the fever produced experimentally by injections of cocain The percentage of blood solids and the red blood cell count increase coincidently with the temperature The return of the temperature to normal is accompanied by dilution of the blood Antipyretic drugs also have been demonstrated in numerous instances to act in harmony with the ideas just outlined The problem of the water content of the blood is truly attaining a new significance in many fields of clinical medicine

RECENT FEATS OF MOUNTAINEERING

The latest news from the Mount Everest Expedition records an ascent by Capt Geoffrey Bruce and George Finch to an altitude of 27,200 feet At this point they were only 1,941 feet below the summit It is stated in the New York *Times* that the mountaineers just mentioned climbed only 400 feet higher than Mallory, Somewell and Norton did on May 21 without oxygen The latter group broke the record of the Duke of the Abruzzi made on Bride's Peak, which was 24,600 feet From a physiologic standpoint alone, these are stupendous personal feats The passive ascent by railway to the top of Pike's Peak at an altitude of only 14,110 feet is productive of noticeable physiologic reactions and, in some persons, of symptoms of respiratory distress Strauch,[9] who has received the experiences of early explorers with mountain sickness, calls attention to the fact that this malady befalls some persons at a lower, and others at a higher altitude, but that for all there is a critical line beyond which escape is impossible In some it may occur at 10,000 feet, while only a very few can venture to 19,000 feet without the experience [10]

The usual explanation of the exchange and distribution of the respiratory gases in the lungs and tissues has involved the view that the gases diffuse from regions of high tension to those of lower tension, and that the membranes interposed are entirely passive in the process This purely physical hypothesis has not passed entirely unchallenged The apparent adaptation of many persons to life under conditions of oxygen tension seemingly too low for the normal functions has long attracted attention and led to speculation Haldane of Oxford has been the foremost scientist to express the belief that an essential factor in acclimatization to altitude consists in a secretory activity for oxygen on the part of the lungs Obviously, if diffusion is the sole force in the interchange, the oxygen pressure in the arterial blood cannot exceed that in the alveolar air

The Anglo-American Pike's Peak Expedition [11] of 1913, however, reported oxygen tensions in the arterial blood greater by from 7 to 44 mm than in the alveolar air This seemed like clear-cut evidence for active oxygen secretion by the lungs into the blood The technic of this work has been assailed Schneider has pointed out that the Scandinavian physiologist Dr Marie Krogh [12] in 1915 established a new diffusion coefficient for the passage of oxygen through a membrane and showed that, *if the figures were correct, it* was possible for diffusion to account for the passage of a sufficient amount of oxygen to supply the body needs up to such altitudes as 24,000 feet

The proponents of the secretory theory have assumed that although the capacity for oxygen may always exist it is called forth only during extreme oxygen lack C W and C H Greene [13] have given it a rigorous test by studying the arterial blood in animals under conditions of breathing air at a greatly reduced oxygen tension The lowest inspired oxygen in one experiment corresponded to an equivalent altitude of 53,000 feet or 10 miles No evidence was secured in any case to indicate the presence of a higher oxygen tension in the arterial blood than was present in the alveolar air When alveolar air was exposed to a simultaneous sample of arterial blood, oxygen was absorbed by the blood Hence Greene concludes that the current conception of a purely physical mechanism regulating the

passage of oxygen through the pulmonary epithelium is confirmed for all stages of anoxemia These now available experimental facts make the performance at Mount Everest all the more remarkable In the absence of "secretory" aids, the supreme importance of a state of high circulatory and respiratory efficiency in order to secure the maximal degree of saturation of arterial blood with oxygen becomes emphasized more than ever for the balloonist, the aviator and the mountaineer

Current Comment

THE ALLEGED INSUSCEPTIBILITY TO INTOXICATION BY POISON IVY

With the advent of the season when rhus dermatitis, following contact with poison ivy, becomes common, a recrudescence of the myths regarding the effects of this plant is certain to ensue The failure of many persons to exhibit symptoms following apparent exposure to toxic species of rhus has presumably been responsible for the widespread belief that some individuals are not susceptible to the poison An investigation by Brown [1] in the Department of Pharmacology at the University of Minnesota justifies the conclusion that there is probably a personal variability in susceptibility depending on temperature, condition of the skin, and many other factors which are not yet understood, [2] but he is also convinced that there is no conclusive evidence of such a state in man as entire insusceptibility to the poison Contrary to the theory of 'desensitization" by internal administration of tincture of rhus, it appears that the susceptibility may be increased with successive intoxications

ROENTGEN-RAY INTOXICATION FROM INJURY TO INTESTINAL EPITHELIUM

Nausea, vomiting, weakness and diarrhea, frequently observed in patients after exposure to large doses of hard roentgen rays, have been ascribed to the action of the rays on the blood and blood-forming organs, because leukopenia, marrow changes and destruction of lymphoid tissue often follow roentgenization Others have thought, however, that the constitutional reaction results from damage to the kidneys, especially since Warthin [3] described changes in the kidneys of patients treated with roentgen rays Recently Warren and Whipple [4] have reported the results of experiments on dogs which indicate that systemic intoxication may be due primarily to injury of the epithelium of the small intestine They found that a unit dose (350 milliampere minutes), given over the thorax with the abdomen shielded, caused no disturbances in the dog, while a subsequent exposure to the same unit dose, in the same animal, over the abdomen, caused a fatal intoxication in four days The time of the appearance of the symptoms of the intoxication coincided with the cell disintegration, becoming pronounced in the second twenty-four hours The changes, which affected chiefly the small intestine, were varying stages of necrosis of the epithelium covering the villi and lining the crypts Only a slight inflammatory reaction was present, and there was little injury to the lymph follicles and Peyer's patches Warren and Whipple believe that the absence of symptoms after thoracic exposure indicates that the blood and bone marrow cells are not primarily concerned in the intoxication because a greater number of these cells are subject to exposure in the thoracic region than in the abdominal In other experiments, McQuarrie and Whipple [5] found that large doses of roentgen rays over the renal region of dogs did not cause any changes in the kidneys or any appreciable disturbances of renal function These experiments on dogs reveal the intestinal epithelium as vulnerable to roentgen rays with resulting intoxication, and the probability is that the epithelium of the small intestine in man may be vulnerable in somewhat the same way In order to avoid harm, these facts should be borne in mind, when roentgen therapy is being administered

DOES THE BLOOD CONTAIN CREATININ?

To this question, the student of physiologic chemistry has been taught to give an affirmative reply The occurrence of creatinin as a normal constituent of the urine is well known, the isolation of the compound being a routine procedure in many laboratories Whence should this demonstrated urinary creatinin come if not from the blood brought to the kidneys? And have not the blood analysts instructed and entertained us with numerous accounts of the variations of the creatinin content of the blood in health and disease, pointing out the diagnostic or prognostic significance of undue concentrations of this nitrogenous product? Strangely enough, biochemists seem to have been content for the most part to accept color reactions in blood filtrates as proof for the actual existence of creatinin in the blood, despite numerous anomalies and discrepancies that have arisen to perplex the analysts It has remained, however, for Behre and Benedict,[6] of Cornell University Medical College, boldly to question the current teachings They are convinced, from analytic evidence which is impressive, that creatinin does not exist in detectable quantities in blood This conclusion seems somewhat revolutionary, though it helps to bring greater clarity to a much confused subject The blood does contain creatin which Behre and Benedict have actually identified by direct methods of examination Moreover, the creatin content increases in the blood when the renal functions are held in abeyance Creatin in abundance is always found in muscle tissue We may therefore assume

for the present that the creatin in the blood represents a waste product discharged into the circulation and awaiting excretion by the kidneys, which convert it into creatinin in the process of elimination The new view "fits the known facts" It explains the increase in blood creatin content when the kidney activities are impaired It renders conceivable that creatin may occasionally escape unchanged into the urine, as has so often been asserted We venture to believe that a new chapter in the solution of the difficult problem of creatin-creatinin metabolism has at length been opened

THE HIGHER EDUCATION OF CHIROPRACTORS

What is your favorite light literature? Detective stories? Mystery stories? Humor? Have you ever read the publications issued by the various species and subspecies of the chiropractic cult—for there is, as you know, a lack of unanimity among the chiropractors One particularly choice piece of contemporary journalism is issued by a chiropractor factory in Fort Wayne, Indiana Its July, 1922, issue makes good hot weather reading The editor discusses a "model bill," recently drawn up by those chiropractors of Indiana who belong to a different subspecies from those represented by the publication in question This Fort Wayne journal views the bill with disfavor It says, with refreshing naïvete

To begin with there is absolutely no need of a Chiropractic licensing and examining board in Indiana today The existing lot of Chiropractors in Indiana cannot be improved upon You are not being persecuted or prosecuted, you are left severely and strictly alone to practice your profession without let or hindrance from any source or any group of any kind In fact, Indiana today is the best Chiropractic state in the entire country Chiropractic conditions are as near ideal as it is humanly possible to approach that condition

But the fact that Indiana is the home of the free, chiropractically speaking, is not the only objection this journal has to the proposed bill It seems that the bill would require applicants for chiropractic examinations to submit satisfactory proof of the possession of a preliminary education, equal to that of a high school Perish the thought! As the editor says

How many Chiropractors in Indiana today could qualify under that rule? Of all the Chiropractors in Fort Wayne I do not happen to know of ONE that is a high school graduate In fact, I believe that the total number in Indiana able to comply with that ruling would be less than two per cent of all the Chiropractors in the state

From the point of view of the owner of a chiropractic "college" the sentiments just quoted are eminently logical It would be entirely unfair to chiropractic schools to insist on matriculants being educated human beings What educated human being would ever attend a chiropractic school? Of course, from the point of view of public interest—but that's another story

Insanity in London—The total number of insane patients in London reported January 1 was 18 349 (7,423 males and 10,926 females), as compared with 17,916 on Jan 1, 1921

Medical News

(PHYSICIANS WILL CONFER A FAVOR BY SENDING FOR THIS DEPARTMENT ITEMS OF NEWS OF MORE OR LESS GENERAL INTEREST SUCH AS RELATE TO SOCIETY ACTIVITIES NEW HOSPITALS, EDUCATION PUBLIC HEALTH ETC)

ALABAMA

Health Board to Use Ex-Service Men—In the fight against malaria and typhoid in Alabama the state board of health is planning to use former service men who are entitled to vocational training and desire to learn sanitary engineering work These men will be placed in charge of the work of drainage clearing mosquito breeding places, and other activities Arrangements have been made with the U S Veterans' Bureau for training a limited number of ex-service men for this work

ARKANSAS

Hospital News—Bids have been opened for the construction of the new St Edward's Infirmary, Fort Smith——A hospital will be erected at Conway at a cost of $50 000——The St Bernard Hospital annex, Jonesboro has been torn down and a brick structure will be erected to replace the frame annex

CALIFORNIA

Physicians Mobilize to Aid Veterans—Six thousand physicians of the state with 300 first-class hospitals at their disposal mobilized, June 29 to aid the disabled war veterans of California in conjunction with the California State Medical Association and the League for the Conservation of Public Health These physicians have offered their services to the soldier organizations and welfare bodies, and have recommended a new system of medical treatment for disabled soldiers that will be put into operation at once It will furnish every wounded veteran in the state with the highest class of medical aid and hospital treatment and will guarantee individual attention and care It is the plan of the physicians to mobilize those affiliated with the two organizations into groups in every community in the state, first for the care of ambulatory sick Any wounded soldier will be privileged to call on any physician in his community affiliated with the mobilization movement, and ask for service If the individual case cannot be cared for by the physician called on the case will be transferred to a diagnostic and clearing house hospital The third division of the system will be devoted to the therapeutic hospitals for the treatment of chronic troubles, such as neuropsychiatric cases and tuberculosis These hospitals have already been established and will be manned by officers of the U S Veterans' Bureau the California physicians furnishing consulting staffs and assisting in the organization and management of the hospitals For those patients who cannot be aided by the three means outlined and who would be classed as hopeless chronic invalids, the final resort will be care for the rest of their lives in comfortable invalid homes for incurable disabled veterans Dr A E Musgrave secretary of the state medical association, officially offered the plan for the physicians at a luncheon called by C J Sullivan secretary of the League for the Conservation of Public Health, June 28 in San Francisco Col Charles R Forbes, director of the U S Veterans Bureau accepted the offer of mobilization of the physicians for himself and President Harding The offer was also officially accepted by Commander Marx in behalf of the Disabled American Veterans of the World War and by State Commander Quinn of the California division of the American Legion

COLORADO

Hospital Dedication—With delegations from many states, the Jewish Consumptives' Relief Society dedicated the new $500 000 building of the sanatorium of the Jewish Consumptives Relief Society at Edgewater, July 9 This new structure was erected where the central building of the sanatorium was destroyed by fire several years ago Dr I D Bronfin is superintendent of the institution

Denver Tuberculosis Society—Under the auspices of the society, a long desired outdoor school has been established, in Denver The school board voted for the school with the understanding that the tuberculosis society should furnish any extraordinary equipment and direct the extracurriculum side of the undertaking Provision is made for measuring

all children in the grade schools of the city and in arranging for the serving of milk to children who are underweight. The Modern Health Crusade has been extended, and, in September, the school board has agreed to bear half the expense of the crusade in the schools.

CONNECTICUT

Epidemic of Typhoid.—Thirty cases of typhoid fever are reported from New Haven and several from New Britain. The health department has issued a warning against eating raw clams and has offered inoculation to those desiring it.

DISTRICT OF COLUMBIA

Personal.—Dr. Thomas Hugh Scott, U. S. Public Health Service, Washington, who recently announced his retirement from the race for Republican candidate for governor of Oklahoma, has accepted the appointment of medical adviser to the U. S. Veterans' Bureau.

Cancer Committee Appointed.—At a meeting of the District of Columbia Medical Society, July 1, a cancer committee was appointed to act with the local committee of the American Society for the Control of Cancer, which is to conduct an educational campaign in Washington during the summer, ending with "Cancer Week," throughout the country, in November. Dr. Edwin A. Merritt was named chairman, the other members being Dr. Albert L. Stavely, Dr. Thomas A. Groover, Dr. Edward M. Parker and Health Officer William C. Fowler.

FLORIDA

Medical Meeting Held on Ship.—The Florida Railway Surgeons Association held their third annual meeting on board the S. S. *Cuba* while en route to Havana for the annual meeting of the Florida Medical Association. The session was held under the presidency of Dr. James H. Pittman, Jacksonville.

GEORGIA

Children's Code Commission.—An act to create the Georgia Children's Code Commission will be presented to the next session of the Georgia legislature, also to provide for the appointment of ten members to the commission who shall be selected by the governor of Georgia. Section 2, reads:

> That it shall be the duty of said Georgia Children's Code commission to study the existing laws of Georgia which in any way affect child life; to study conditions of child welfare in the state; to study the laws of other states and to consult authorities in this and other states and to draft for presentation to the succeeding legislature such laws or amendment to the existing laws as will better afeguard the welfare of children in this state.

The commission, whose members will hold their term of office for five years, shall consist of one superior court judge, one member of the house of representatives, one state senator, and a member or representative from each of the following organizations: Federation of Women's Clubs, League of Women Voters, State Council of Social Agencies, state board of health, state board of public welfare, state federation of labor and the state department of education. The members of the commission will receive no salary or remuneration for their services.

ILLINOIS

Free School Clinics.—Drs. Elizabeth B. Ball and Elmer M. Thomas, of the state department of health, held a series of clinics in the Kane County schools, June 12-27. These clinics were held daily and were free to the public.

Chicago

Chicago Physician to Aid Russians.—Dr. George B. Hassin, neuropathologist and professor in the University of Illinois Medical College, left July 1, for New York, and will sail soon for Russia to aid in relief work of the American Medical Aid Society. Dr. Hassin formerly practiced in Siberia.

INDIANA

Hospital News.—Bids have been let for the new Adams County Hospital to be erected at Berne.——The cornerstone of the children's building at the state sanatorium, Parks Lodge, was recently laid.——The new sanatorium at Dillsboro was formally opened, June 24. The new building was erected at a cost of $200,000, and has 120 rooms fitted with modern conveniences.

Riley Hospital for Children.—This week ground will be broken on the first unit of the James Whitcomb Riley Hospital for Children, which is to be erected on a site between the Robert W. Long Hospital and the City Hospital. Arrangements have been made for the purchase of the ground lying between these institutions, so that all of the buildings in the hospital group will be joined, and the intervening space will be available for use as a convalescent park. In the first unit, provision will be made for the care and treatment of one hundred bedridden children and the first building, when completed and equipped, will represent an expenditure of $500,000. Credit for the initiation of this plan is given to Dr. Lafayette Page, president of the Indianapolis Medical Society, who first called a committee to outline a campaign in 1917. The entire project will cost approximately $2,000,000, the money to be raised through popular subscriptions conducted throughout the state. When completed the hospital will have facilities for the care and treatment of 350 children. According to the plan, the hospital will be maintained by the state, and children from any county, legally resident of the state may be admitted for treatment by the judge of any circuit, juvenile or criminal court. In preparing the plans, the committee of architects and physicians visited all of the well known children's hospitals in the country and it is hoped to have the new institution representative of the best type of hospital in its special field.

IOWA

Banquet for Physicians.—The Van Buren County Medical Society recently gave a complimentary banquet, at Des Moines, in honor of Dr. George R. Neff and Dr. Thomas G. McClure, to celebrate their fiftieth year of active practice in Iowa. Dr. Roger N. Cresap was toastmaster.

County Society Anniversary.—The fiftieth anniversary meeting of the Marion County Medical Society was held in Knoxville, June 22. In the afternoon, the physicians and dentists met in scientific session. Dr. John W. Martin, Des Moines, read a paper on 'Diagnosis of the Acute Abdomen" and W. L. Harlan, D.D.S., Knoxville, spoke on "Our Relation from the Dental Viewpoint."

Personal.—Dr. Charles S. Chase has resigned as professor of materia medica at the University of Iowa, Iowa City, following thirty years of service. Dr. Chase will retain his connection with the dental college and the school of pharmacy. Dr. O. H. Plant will succeed Dr. Chase in the department of materia medica.——Dr. Lucius F. Hoyt, Jefferson, has just returned from the Methodist Hospital, Des Moines, where he had his left arm amputated just below the shoulder.——Dr. George L. Prentice, Pulaski, has been appointed physician to the Indiana State Soldiers' Home, Lafayette, effective, July 1.

KANSAS

Kansas State Board of Health.—At the annual meeting of the board held in Topeka, June 30, Dr. Joseph E. Hawley, Burr Oak, was elected president. Dr. Jacob J. Entz, Marion, vice president, and Dr. Samuel J. Crumbine, Topeka, was elected secretary of the board.

KENTUCKY

Traveling Trachoma Clinic.—A fully equipped hospital wagon, drawn by four mules, is the conveyance used by Dr. Charles B. Kobert, director of the bureau of trachoma and prevention of blindness of the state board of health, for his six months' trip through western Kentucky. Dr. Kobert, who started on his trip early in June, will give free treatment to all persons suffering from eye diseases. On the trip made in the summer of 1921 Dr. Kobert operated in eastern Kentucky on more than 4,000 patients having trachoma. Congress has made an appropriation of $200,000 for a new trachoma hospital at Pikeville.

LOUISIANA

Personal.—Dr. Henry Ladd Stickney, U. S. Veterans' Hospital, Dwight, Ill., and formerly in charge of the surgical service at Fox Hills Hospital, Staten Island, N. Y., has been appointed superintendent of the Presbyterian Hospital, New Orleans, and reported for duty, July 1.——Dr. Ernest S. Lewis was recently elected president of the Louisiana Antituberculosis Association at the annual meeting in Baton Rouge.

MAINE

Fund for Medical Scholarships.—At the recent meeting of the Maine Medical Association, it was announced that the interest accruing on a bequest made some years ago to the Bowdoin Medical School, now out of existence, will be used

in providing medical scholarships for students from the state of Maine The president of Bowdoin College is charged with the management of the fund and applications for the scholarships are to be made to him

Public Health News—Under the auspices of the Maine Public Health Association, a luncheon conference was held recently in Augusta, under the presidency of Dr Elmer D Merrill, Foxcroft, at which more than thirty organizations were represented The health program for the next three years in Maine was outlined by Dr Merrill, who stated that this will include an extension of the visiting nurse service throughout the state, the holding of clinics for Maine physicians, the extension of the Modern Health Crusade in the schools, the development of fresh air schools, industrial nursing and special campaigns for the eradication of tuberculosis, cancer and social disease, and for the promotion of dental and child hygiene, baby welfare and the conservation of vision Among those who attended the conference were Dr Clarence F Kendall state health commissioner, Dr Benjamin L Bryant secretary of the Maine Medical Association, Dr A Thomas, state superintendent of schools, and Dr Donald B Armstrong executive officer of the National Health Council, who was the guest of honor

MARYLAND

Drive Against Diphtheria Started—In an effort to make diphtheria a negligible menace to public health in Baltimore city, the health department has sent to Baltimore physicians communications urging general use of toxin-antitoxin, in order to convey immunity to the disease Under the direction of Dr C Hampson Jones, health commissioner, and Dr John F Hogan head of the bureau of communicable diseases, a plan of procedure has been worked out to make diphtheria as light a factor in the health problem as smallpox has become through similar preventive measures Dr Jones made it clear that no immediate serious diphtheria situation exists The reason for the campaign at this time is to secure wide use of the department s plan now so that schoolchildren may obtain immunity before school begins and the active season for the disease returns While adults can obtain the same treatment children are the chief concern because of their susceptibility to the disease

MICHIGAN

Michigan Health Officers Association—At the annual meeting of this association the following officers were elected for the ensuing year president, Dr Guy L Kiefer, Detroit, vice president, Dr David Littlejohn, Ishpeming and secretary-treasurer, Dr William J V Deacon, Lansing

Michigan Association of Industrial Physicians and Surgeons—At the annual meeting of the association in Flint recently, Dr Guy Kiefer Detroit was elected president, Dr Clarence S Gorsline Battle Creek, vice president, and Dr Grover C Penberthy, Detroit, secretary-treasurer

Donation for Relief Work—The food packages distributed to Russian physicians have thus far amounted in value to $70,000 The latest allocation of $20 000 for that purpose was made possible through a gift of $35 000 by William Bingham Jr, an American Two thousand American Relief Administration food packages have been set aside for the benefit of starving physicians who are aiding the relief administration in its inoculation program Inoculation against typhoid, two types of paratyphoid cholera and smallpox is being carried on at every point to which American food is distributed More than 10 000 000 Russians will be immunized following the completion of this program

Foreign Students and the Immigration Law—The executive committee of the American Association of University Professors recently adopted a resolution urging that Congress be petitioned to amend the existing 3 per cent immigration act by exempting from its provisions all bona fide foreign students, stating that the actual operation of the present law has been attended with such deplorable annoyance to incoming students as to lower the prestige of the United States as a center of education The resolution further states

> WHEREAS The omission to exempt bona fide students desirous of entering American institutions of learning from the operation of the present immigration law is probably due to inadvertence inasmuch as such students are expressly exempted from the operation of the Chinese exclusion act and the agreement with Japan and that in case such amendment be not made effective before September 1, the government be petitioned to cause the adoption by the Bureau of Immigration of such administrative rulings as will preclude the possibility of incoming students being sent to Ellis Island or other detention stations

To Renew Fight on Cancer—The American Society for the Control of Cancer has received its certificate of incorporation in New York State Dr Francis Carter Wood, one of the incorporators, announces that the society s field representative will confine his efforts for some months to Pennsylvania, Iowa and Illinois, which have not yet been fully organized The society has increased its membership more than 200 per cent during the last three years, and now has about 2,000 members A grant of $26,750 has been made to the society by the Commonwealth Fund which made possible the organization of the field work, and Mrs M Lasker and family have set aside $50 000 as a permanent endowment fund Five new names have been added to the board of directors Melville E Stone, Dr Frank Billings, Chicago Dr W W Keen Philadelphia, Postmaster General Dr Hubert Work and Dr W T Huntington, San Francisco Dr Edward Reynolds of Boston was named as chairman of the council

Hearings on Social Hygiene Board Bill—Hearings before the House Committee on the Judiciary on the bill introduced by Representative Kahn of California for the transfer to the Department of Justice of the law enforcement functions formerly discharged by the Interdepartmental Social Hygiene Board, with reference to the repression of prostitution in localities where armed forces of the United States are stationed brought out a practical unanimity of opinion in support of the measure The recognized fact that the board would cease its activities on June 30 because of the absence of any appropriation for carrying forward its work limited discussion closely to advisability of continuing its law enforcement activities under federal auspices and, if so continued, of vesting them in the Department of Justice There was unanimity as to the desirability of such activities being continued and substantial agreement as to the expediency of charging them to the Department of Justice rather than to either the Army, the Navy, or the Public Health Service Among the speakers in support of the measure were Major-Gen W M Ireland Surgeon-General of the Army, Dr Hugh S Cumming, Surgeon-General of the United States Public Health Service Dr Valeria H Parker, executive secretary of the Interdepartmental Social Hygiene Board, and Dr William F Snow, secretary of the American Social Hygiene Association

LATIN AMERICA

Argentine Physicians—According to a recent article in the *Boletin del Sindicato de Medicos de la Republica Argentina* there are at present in that country about 5,000 physicians Assuming generously a population of 10 million this would make one physician for each 2,000 inhabitants Since 1914 1 508 physicians have graduated from the Buenos Aires Medical School and since 1921, fifty at Cordoba

Personal—Dr Filiberto Rivero of Havana is visiting clinics in this country——Dr Eliud Garcia Treviño and Dr Aliber Garcia Treviño of Monterey are taking postgraduate courses in Chicago and Philadelphia respectively——Dr Franklin P Pyles an American physician, now practicing at Rio de Janeiro Brazil is visiting in Chicago It is claimed that Dr Pyles is the only English-speaking physician at Rio

Retirement of Professor Coronel—The *Anales de la Sociedad Medico-Quirurgica del Guayas*, of Guayaquil commenting on the fact that Dr J Coronel has resigned his chair of internal medicine in the University of Guayaquil relates that he has been in practice in Guayaquil for forty-seven years and on three occasions has been given the official thanks of the national public health service for his various services He was also awarded a gold medal por Merito Profesional,' by the first national medical congress held in Ecuador, which met at Guayaquil in 1915 He recently founded a scholarship in medicine and in law at the University of Guayaquil and is honorary president of the Sociedad Medico-Quirurgica del Guayas

FOREIGN

Royal College of Surgeons of Ireland—At the annual meeting of the college Sir William I de C Wheeler was elected president, Dr Robert C B Maunsell, vice president, and Sir A H Ormsby, secretary

Posthumous Tribute to Keating-Hart—The French government has published a statment citing the devoted services during the World War of Dr Keating-Hart, the well known specialist in electrology and radiology, who introduced fulguration and who died last January at Paris He continued his work although suffering from the effects of roentgen injury, requiring two operations The *Journal Officiel* of June 20 announces that his name has been placed on the records as chevalier of the Legion of Honor It is said of him that he "wedded the long electric spark to the high frequency current"

Dramatization of Pasteur—A play by M Sacha Guitry entitled "Pasteur" has recently been produced in London This play was originally produced in Paris in 1919 The scenes depict Pasteur in his study in 1870, in the Paris Academy of Medicine, where he vigorously combats an attack on his theories, with the boy Joseph Meister, who has been bitten by a dog and comes for treatment to Pasteur, who sends for a physician to perform the inoculation, at his home in the country, and finally in the crown of his career, at the reception given him by the president of the republic, in the amphitheater of the Sorbonne

Postponement of Second International Congress on Comparative Pathology—This often postponed congress, which was finally definitely appointed for Sept 20, 1922, has been postponed again till next spring The reason is said to be "difficulty in organization," which means, probably, difficulty in making the congress truly international in scope The topics appointed for discussion are regeneration of nerves, cancer, deficiency diseases, and diseases with a filtrable virus, but communications on a large number of other subjects have already been announced The *Paris Medical* of June 24 contains a list of fifty-five

Socety for the Study of Venereal Disease—The Medical Society for the Study of Venereal Disease was formed in London, June 9 Dr David Watson, Glasgow, presided at the meeting It was agreed that the society should not express its corporate views on any subject of administrative or political interest, unless invited to do so by the government, and that, in the event of such invitation, the views expressed should be those of 80 per cent of the members voting on a referendum The annual general meeting will be held each year in July Local divisions of the society will be formed and appoint their own officers Dr Robert Forgan agreed to act as secretary until the first regular meeting of the society this month

Laryngeal Tuberculosis in the Netherlands—The Netherlands Laryngologic Society has been collecting data on the prevalence of laryngeal tuberculosis, and has found that it is overlooked in an amazingly large percentage of cases In Leiden, where laryngologists are connected with the consulting dispensaries, the proportion of laryngeal tuberculosis cases was 6 per cent while it was reported from other towns as only 0 4 per cent in 15 240 tuberculous examined by nonspecialists In the sanatoriums that responded, the proportion was reported as 13 per cent They urge the necessity for specialist examination of the larynx in the preventoriums as a routine practice, regardless of whether the applicants complain of throat symptoms or not

Personal—Dr Edwin Bramwell has been appointed to the Moncrieff-Arnott chair of clinical medicine at the University of Edinburgh, to succeed the late Prof Francis D Boyd—— Dr Hugh Norton has been appointed to the chair of medicine at Anderson College of Medicine, Glasgow, to succeed Dr John M Cowan, who resigned recently——Mr Thomas H Openshaw, senior surgeon of the London Hospital, has retired from the active staff after forty-five years' connection with the medical school——Prof Hijmans van den Bergh delivered a London University Lecture, June 21, on "The Pathology of Hemoglobin"——Dr John C McVail has been awarded the Jenner Medal of the Royal Society of Medicine ——Mr Evelyn D Telford, lecturer in practical surgery at the University of Cambridge, England, has been appointed professor of systematic surgery at the University of Manchester to succeed Prof J W Smith, who will vacate the chair in September

The Graduate Courses in Heliotherapy at Leysin—THE JOURNAL mentioned on page 1932, June 17, 1922, Rollier's courses which are held in August each year The next course opens Aug 15, 1922, and consists of twelve lectures on the various aspects of heliotherapy and roentgenographic control, with practical demonstrations in some of the various sanatoriums in his charge The course is gratuitous, the charge for room and board is 12 francs a day The lectures are given by Rollier and six of his assistants Rollier's own subjects are "The Practical Application of Sunlight in Treatment of Tuberculosis", "Heliotherapy of So-Called Surgical Tuberculosis', "Work in the Treatment of Tuberculosis, and the Future of the Convalescents', 'Preventive Heliotherapy," and demonstrations of results in the "Sun School" American physicians are welcomed Applications are received up to the two weeks before the course opens Address Dr Rollier, Leysin-Village, Switzerland This is the second year of these courses

Tribute to Marchiafava—Prof E Marchiafava, having reached the age of 75, retired, June 5 from the chair of pathologic anatomy at the University of Rome after forty-eight years of continuous incumbency A fund has been endowed in his name by contributions from royalty, the city of Rome, the Italian Red Cross, the public health service, the hospitals and banks and others, to found scholarships at the University of Rome A number of addresses were made by delegates from various scientific societies and Marchiafava's numerous contributions to science were enumerated, his initial research on malaria and his leadership in the campaign against malaria in Italy, his discovery of the estivo-autumnal parasite of the cause of melanemia and his studies in syphilis, tuberculosis, alcoholism, etc The city of Rome has always regarded him as the one responsible for having freed it from malaria One of his latest works was the foundation of the Asilo Antimalarico Communale as a home in Rome for the children of families living in the malaria infested marshy districts in the region A tablet was placed on this building by the community when it was inaugurated last year, paying tribute to Marchiafava as the originator of the project

American University Union—George E McLean, director of the American University Union in London, announces that since the British universities have recently given renewed attention to advanced and research work and have established the Ph D, or D Phil degree (with American graduate students in mind), the union is now able to advise and introduce American graduate students so that, without loss of time, they may proceed with their work in the British universities and gain admission to the reading room of the British Museum the public record office and other archives and collections Among the functions of this office are the receipt and forwarding of mail, keeping a list of boarding houses, and posting notices of public lectures and amusements Round table conferences are held by British scholars and public men during the season The Universities' Bureau of the British Empire the Office National des Universites et Ecoles Françaises and the Danish Students' Bureau are housed in the same building with the American University Union A common library and reading room is located in the building, and visiting American scholars are advised to register, free of charge, immediately on their arrival in London

The New Journal, "Social Defense"—The foundation of the Italian Institute of Hygiene by Prof E Levi of Rome has been already mentioned and the wide scope of its efforts commented on It aims to compile statistics, coordinate efforts of all kinds of organizations public and private, and maintain propaganda to promote public and private health, safety, and moral and physical well being Most of the leading statesmen and clinicians of Italy are on the committee in charge, and pamphlets and films to aid in the work are being published, and the monthly journal *Difesa Sociale*, has been founded Professor Levi desires to emphasize in this publication American methods of public health administration and personal hygiene, in addition to its other aims The first two numbers contain among other articles one by Grassi on "The Present Status of Malaria," and others by Levi on "The Value of the Race and Social Defense' and "The Human Balance-Sheet of the World War' The agitation on behalf of the defense of human beings against avoidable ills is reviewed as it proceeds in various countries The subscription to the *Difesa Sociale* is 50 liras The official title of the institute is the Istituto Italiano d Igiene, Previdenza ed Assistencia Sociale The address is Via Condotti 8 Rome

Deaths in Other Countries

Prof **C U Zanetti**, director of the Institute of Pharmacological Chemistry of the University of Parma——Prof **Jenö Holzwarth**, who held the chair of radiology in the University

of Budapest——Prof Edmund Weil of Prague, died of typhus contracted by infection in his laboratory at Lemberg, where he was working in response to an appeal from the Polish government——Dr Eladio Eguren, of Rosario Argentina, member of the municipal council——Dr A de Barros, professor of nervous diseases at the medical school of Bello Horizonte, Brazil——Dr N Coppola, professor of radiology and electrotherapy at the University of Naples, another victim to the early zeal in the application of the roentgen rays aged 42 Parts of both hands were amputated at various times and the dermatitis finally became malignant, rebellious to all treatment——Dr Armand Imbert, of the medical faculty at Montpellier

CORRECTION

Seattle Health Officer—In THE JOURNAL, July 1, it was stated that Dr Rowe France would succeed Dr Hiram M Reed as city health officer Dr Reed writes that his term of office will not expire until March, 1924

Government Services

Organization of Reserve Hospitals of the Army

June 30 Surgeon-General Ireland authorized the organization of a general hospital to be known as General Hospital No 21 Organized Reserves at the Washington University School of Medicine, St Louis This unit served during the World War as Base Hospital No 21 with the British Expeditionary Forces Lieut-Col Malvern Bryan Clopton, M O R C, is to command this unit and is now engaged in enrolling the number of reserve officers necessary to fill the positions of the unit called for by tables of organization This is pursuant to the policy of the Surgeon-General to revive and perpetuate in a general way the units that served in the World War, originally organized by the Red Cross New units will be given new numbers During the war, these units served as mobile hospitals and base hospitals and they will now retain their former numbers as surgical hospitals and general hospitals They are no longer Red Cross units but pertain to and are part of the military establishment This is the first new reserve hospital to be authorized by the Surgeon-General to meet the medical needs of the military establishment in case of emergency

The Surgeon-General of the Army is now required to organize, largely with medical department reserve officers, the evacuation and surgical hospitals that will function under the control of tactical armies and the general hospitals convalescent hospitals, convalescent camps, station hospitals and the laboratory and medical supply services of the communications zone and home territory It is the desire of the War Department that these reserve hospitals take on a local distinction which will pertain to the medical college or approved internship hospital that is to foster the unit The officers of these units are to be selected within the foster institution or in the community subject of course, to the laws and regulations as to eligibility for appointment in the Officers Reserve Corps The nurses of these units will be taken from the enrolled nurses of the Red Cross nursing service, which constitutes the nursing reserve of the army It is not intended at this time to recruit the reserve enlisted men nor to issue property, the idea being that there will be a reserve organization of commissioned personnel at the parent institution, which can readily be expanded in case of necessity, to an army hospital

LIABILITY FOR SERVICE

Considerable misunderstanding exists as to the liability of reserve officers being called to active duty The law of June 4, 1920 provides that except in time of a national emergency expressly declared by Congress no reserve officer will be employed on active duty for more than fifteen days in any calendar year without his own consent The War Department does not contemplate calling reserve officers to active duty for training or other purpose for fifteen days each year For some time to come, the training must be voluntary, owing to the limited appropriations A reserve officer called to active duty for training purposes during any calendar year and on whom such duty for business or other good reason would work a hardship, will on request be exempted from such tour of duty The Surgeon-General recognizes the drawback to membership in the Medical Reserve Corps, if professional and business men who have had war service are inconvenienced by call to compulsory duty in time of peace each year, and does not contemplate any such policy

REQUIREMENT FOR PROMOTION

Training, however, is a requirement for promotion to field rank and higher grade, if the applicant has held no position commensurate with the position he is required to fill on promotion In organizing these units, it is to be understood that reserve officers are not required to hold the rank called for in tables of organization, as office and rank are separate and distinct

Personnel of the Reserve Corps

The Medical Department Reserve Corps now numbers approximately 12,000 officers, and applications are coming in rapidly A great many former officers have recognized the advisability of joining the reserve corps at this time owing to the regulations in regard to promotion, and also in view of the provisions of the Pay Act of the army which gives a reserve officer one-half time credit for all inactive service in the reserve corps when called to active duty, in addition to the base pay of his grade

Units to Be Organized

The Surgeon-General is now undertaking the organization of the following units pursuant to instructions of the Secretary of War three army medical headquarters, one general medical headquarters, two section medical headquarters, one specialist group thirty-six surgical hospitals (former mobile hospitals) forty-five evacuation hospitals, 165 general hospitals, twenty-four station hospitals (former camp hospitals) three convalescent hospitals, twelve hospital center headquarters, twelve convalescent camps, thirty-seven hospital trains three air service physical examining units, five general dispensaries three army medical laboratories, twelve hospital center laboratories two communications zone medical laboratories, one general medical laboratory, nine medical supply depots two intermediate medical supply depots, and two base medical supply depots

Summer Camp for Veterans

Disabled veterans of the World War Chapter 1, Minneapolis, in cooperation with the U S Veterans Bureau, have taken over the management of the Big Island Summer Camp at Big Island, Minn for the season A large radio outfit additional boats and a swimming instructor and recreational supervisor have been added to the camp, which opened June 19 and will stay open until September 2 There are accommodations for 180 men each two weeks, and the charge for all expenses is $15 for that period

Reduction in Army Medical Corps

Reduction of the commissioned personnel of the army as a result of the War Department appropriation act, fixing the minimum number at 12530 and providing for a board to select officers to be discharged or eliminated from the service will result in the reduction of the medical corps by 145 officers The present personnel of the corps is 1,128, and there is no doubt that many efficient officers will be involved The dental corps will suffer a severe blow also, although only seventy-seven officers will be eliminated from this service Included among these officers will be two or three colonels from five to seven lieutenant-colonels, from twenty to twenty two majors and the remainder the captains and lieutenants None of these officers have sufficient active service to their credit to permit their transfer to the retired list and unless retired for physical disability they will have to be discharged with a year's pay The medical administrative corps also will have a disastrous blow in this proposed elimination The corps will lose sixty-six of its 138 officers All of them were noncommissioned officers of long service and most of them could have retired with more pay than is now possible since they now have only the choice of being discharged with a year's pay or being demoted to warrant officers and retired as such Some of them have been in the medical corps of the army from thirty to thirty-five years and could have retired as enlisted men at $110 a month or after June 30 at $135 a month Now the best they can hope for is retirement as warrant officers at $75 a month The

provision of the act stopping all promotions in the army for six months has also served to lower the morale of the Medical Department

Contract for Jefferson Barracks Hospital Awarded

The contract for supplying the complete mechanical equipment for the U S Veterans' Bureau hospital to be erected at Jefferson Barracks, Mo, has been awarded to the S Faith Company, Philadelphia, for $311 000 The hospital will cost a million dollars According to Assistant Secretary of the Treasury Clifford the contract will be given for the construction of the buildings in the near future

Medical Treaty Between France and Italy

On account of their proximity to Italy, the cities of Lyons Nice and Marseilles admit many Italian patients to their hospitals, and for a similar reason the hospitals of Bordeaux are crowded with Spanish patients The great number of Spanish women entering the obstetric clinics had already excited curiosity before the war, and an inquiry revealed that many of these women left their country during the last months of pregnancy to be delivered in France, especially in Bordeaux The Italian colony of Marseilles comprises more than 100 000 and 52 per cent of the total number of patients treated in its hospitals are of that nationality This is a heavy financial burden on the city Thus a Franco-Italian treaty has been ratified to settle the question According to the terms of the treaty, the citizens of the two nations who, on account of pregnancy or confinement, or for any other reason, are in need of help and any other medical assistance will be treated in the territory of the other contracting party as far as the application of social welfare laws are concerned in the same manner as the citizens of that country, either at home or in hospitals Money expended for treatment by the country in which the patient resides will not be reimbursed in any case by the country, department, province, commune or public institution to which the patient belongs, as long as an acute disease certified by the attending physician as such, renders medical assistance necessary *In other cases, including* relapses, reimbursements will be made for the period following the first forty-five days of treatment The country in which the patient lives will continue to bear the cost of medical care without reimbursement in cases concerning (1) the care at home or in hospitals of the elderly, cripples *and incurables having* at least fifteen years of constant residence in the country in which they enjoy the benefit of a relief pension or the gratuitous shelter of the home for the aged (this will be reduced to five years when the incapacitation is due to an occupational disease) and (2) all those who are ailing, the insane and other patients having five weeks' residence in said country As to those who cannot fulfil the residence requirements indicated, the government, after the forty-five days have elapsed, will as it sees fit and upon advice from the other government, either deport the patient if his condition permits, or charge the cost of the treatment to the country from which he comes

The two governments agree each to see that industrial centers having a large number of workmen of the other nationality are equipped with all the necessary means to take care of those who are ill or suffering from accidents, as well as their families When the cost of treatment given at home in hospitals or infirmaries *is borne by the employer*, workers will have the right to take advantage of it without any reimbursement by either country Benevolent or social welfare associations organized by Italians in France and by the French in Italy, and mixed associations in one or the other country, organized according to the laws of the country, will enjoy the rights and advantages guaranteed to French and Italian associations of the same nature

Protest by Antipornographic Societies

The Federation des societes antipornographiques recently held its third congress in Lyons and commented on certain formulas printed in the folders pertaining to prophylactic education delivered to young recruits at the time of their medical examination The federation believes that the best prophylaxis against venereal diseases is a prophylaxis having a character essentially moral Therefore, it requested the minister of war not to deliver this literature "that seems to make young men believe that debauch is inevitable at their age and that venereal diseases are without importance as long as medicines ward off danger, stating further, that this procedure is not scientific The minister of war transmitted the request to the Societe de prophylaxie sanitaire et morale, and it was easily demonstrated that in the folders in question moral prophylaxis has not been neglected For instance one may read the following advice 'Above all things, be fearful of ruining your health and future in debauch, for heedless sexual intercourse outside of marriage may entail dreadful diseases Therefore the society emphasized the necessity of continuing this prophylactic education of recruits, which in no way can be considered as immoral

The Fight Against Cancer

The minister of hygiene, charity and welfare recently appointed a commission to combine the works and efforts pertaining to the etiology, pathogenesis clinical study, therapeutics and prophylaxis of cancer The honorary president of the commission is Dr E Roux of the Pasteur Institute The president is Professor Quenu and the vice presidents are Professors Calmette, Roger, Letulle, Delbet and Hartmann

The French and American Medical Standpoints

In previous letters, I had the opportunity of showing the striking differences existing between French and American institutions and customs In the United States, public interest is placed above all, but, unfortunately, in France individualism is the dominant spirit I recall what Dr E Roux of the Pasteur Institute said regarding the slowness of the propagation of hygiene in France "The Frenchman's individualism does not lend itself to general social movements and concerted and continued efforts Hygiene requires that an individual submit to discipline for the common welfare"

The same spirit of individualism is also an obstacle to the realization among our professional associations of movements similar to that of the American Medical Association In a letter published in the last number of the *Gazette des hopitaux*, Dr Faxton E Gardner of New York shows also by a few examples "how often the medical standpoint differs in France and America" For instance the medical syndicate of the department of the Seine recently adopted the following resolution concerning consultations of pregnant women 'Visiting nurses would only constitute a new type of functionaries that the people would have to pay France *having* need of raising its birth rate, it is preferable to encourage these women to fulfil the duties of motherhood *Not only* are these functionaries useless, but they could also be harmful to expectant mothers and physicians' It is with reason that Dr Gardner remarks that not one medical association could be found in the whole United States that would even partly agree with a declaration of that kind, in which women are told rather disdainfully and without circumlocution not to compete with men, and to be satisfied with the duties to which

the stronger sex has always been pleased to confine them, those of motherhood and housekeeper

Gardner gives another example in which American opinion differs absolutely from French opinion He refers to the problems concerning bovine tuberculosis which have been recently taken up again in France following a request by the council of hygiene of the department of the Aisne asking the compulsory application of the tuberculin test to cows whose milk is sold to the public and demanding that all cows with positive reaction be sent to the slaughter houses This proposition was not accepted by the Academy of Medicine, and it stated that the only way of warding off the transmission of tuberculosis by milk was to boil the milk Dr Gardner compares this with the radical legislation of the state of New York, and remarks that once more in France principles of hygiene have been obliged to give way to considerations of economic opportunism

A New Hospital Society

Physicians and surgeons of the Saint-Antoine Hospital in Paris have just organized a society called the "Amis de l'hopital," the aim of which is to make wards more attractive and the stay of patients less distressing by decorating the wards with flowers and plants by giving better food to patients, and by performances similar to those soldiers enjoyed in the war hospitals Moreover the society helps families of patients who are very often deprived of resources through the sickness of one of the heads of the family and takes care of convalescents after they leave the hospital

NETHERLANDS

June 7, 1922

Hospital Congress

Several members of the board of directors of the largest hospitals in the country gathered in Utrecht under the presidency of Mr Wortman to discuss the various advantages that might be derived from a general congress in which questions pertaining to hospital organization would be taken up It is probable, judging from present reports, that the project will mature

Medical Directory

The 'Geneeskundig jaarboekje voor Nederland" for 1922 has just been published This directory gives a list of hospitals and sanatoriums and all information that may be of interest to the medical profession The Netherlands today has 3495 physicians, 381 dentists 925 midwives and 635 druggists The number of students in various medical faculties reaches 2079, including 267 women students

Annual Meeting of the Netherlands Medical Association

The Nederlandsche Maatschappij tot Bevordering der Geneeskunst will hold its session at Maestricht July 2 4 On account of the proximity of this city to the Belgian frontier, the organizers will take the participants to Spa during the congress

The Cancer Institute

Judging from advices received from Bandong (Dutch East India), it seems that the project of constructing a research institute for cancer is making progress This institute is to be annexed to a large public hospital where patients will be sheltered The laboratory will be kept up by the income derived from an endowment of 50,000 florins

The Fight Against Malaria in Northern Holland

The committee appointed to combat malaria has made some interesting reports, among which is one from Professor Swellengrebel who, during 1920-1921, made researches on infection by anopheles A careful examination of 5,093 mosquitoes obtained near contaminated houses has shown that the insects were infected, particularly during the months of September and December During that period, 6 per cent of the insects are infected, and this serves to prove that the killing of mosquitoes must be done in the fall On the whole, the fight seems to be successful, as the number of malaria cases dropped from 5,000 in 1918 to 500 in 1921

Home for Convalescent Railroad Employees

The railway administration intends to purchase the Villandry property of forty-nine acres near Nimeguen, for the erection of a home for convalescent railroad employees A temporary sanatorium was built in 1921 on the same site, and it sheltered this year 180 homeless men

PRAGUE

Death of Edmund Weil

Prof Edmund Weil of the German medical faculty in Prague died, June 15 of typhus fever Science loses in him one of the best students of the problems of immunity He has become known through his researches on the role of white blood cells in the mechanism of immunity, in which he followed the lines indicated by his teacher, Prof Oskar Bail He devoted most of his life to the study of typhus fever, and was one of the discoverers of the Weil-Felix reaction, which has become an invaluable means of diagnosis in the fight against typhus fever During the World War, he was engaged in these studies and he continued them after the armistice Having succeeded in cultivating the virus, he began studying in detail the lice and the processes which the virus undergoes in their bodies He was just about to make the final step in his discoveries and proceed to the immunization of man He went to Lemberg in order to have fresh typhus material always available When inoculating an animal intraperitoneally, he sprinkled his eye with an emulsion of the intestines of infected lice which he was injecting He paid no attention to the accident and, having finished his experiment, returned home Exactly on the eleventh day after the accident, he developed typhus fever He died in three days His death is the more tragic in that he left his life's work unfinished just at the stage when it promised to achieve its final aim in the immunization of man against one of the most deadly diseases His assistant Dr F Breinl who has been working with him for several years, is preparing his material for publication and will continue the research as Professor Weil had outlined it

Congress on Social Medicine

A social medicine congress was organized, June 4-7, in Ruthenia, by Czechoslovak physicians who went to Ruthenia two years ago when it became a part of the Czechoslovak republic subsequent to the World War The territory has been neglected so that it has become a focus of endemic infectious diseases such as typhus fever and smallpox Two years of hard work has brought very fruitful results The contagious diseases have been stamped out, and now social diseases form the most important problem in the public health campaign Because the local workers felt that they were not competent to deal with these problems, they called the best of the public health workers to Ruthenia to familiarize them with the local conditions and to seek their advice how to attack the social diseases most efficiently The congress held its session in five sections, the child welfare and tuberculosis sections being the most important ones In the child welfare section the discussion turned on the question as to where

child welfare work should be concentrated Some of the members felt that it should be concentrated around institutions like hospitals, while others emphasized the importance of preventive child health centers as they have been developed by the American Red Cross The second group has been able to defend its stand, so that the final resolution, which was accepted almost unanimously, recommends that all child welfare be concentrated in health centers and that institutions be looked on as necessary, but less important adjuncts in the struggle for better health of children The chief topic for discussion in the tuberculosis section was the fight against tuberculosis among railroad employees, which has been inaugurated on a large scale by the health section of the ministry of railroads An extensive survey of tuberculosis among this group of employees has been made, resulting in a number of specific recommendations for constructive work against tuberculosis The congress has been well organized and will certainly be a source of encouragement to the local workers On the other hand, it has been a rare opportunity for the guests from the other parts of the Czechoslovak Republic to acquaint themselves with the local conditions in Ruthenia which differ greatly from the conditions prevailing elsewhere in the Czechoslovak Republic

Tuberculosis Congress

The Czech Scientific Tuberculosis Society will hold a congress in Prague on the scientific problems of tuberculosis in the spring of 1923 This society, which was founded two years ago for promoting the research in tuberculosis, has done a valuable piece of work in promoting interest in the scientific questions connected with the fight against tuberculosis It holds its sessions regularly every fortnight, and a specific topic is discussed It has succeeded in acquiring a considerable sum of money for the support of scientific research in tuberculosis A special research laboratory of the society is being equipped in the bacteriologic institute of Prague University The initiative of this society has been proved, since there is scarcely a department at the Prague medical faculty in which there is not someone at work on a special topic which he is preparing for the tuberculosis congress in 1923

Adulteration of Pharmaceuticals

At a time like this, when deception and graft are found on every hand it is not surprising to note that pharmaceuticals are adulterated Repeatedly, the discovery has been made here that in place of cocain arsphenamin, santonin and other drugs, preparations of inferior value are sold Instead of arsphenamin, gypsum colored with brickdust is furnished in ampules, and as a substitute for santonin a buyer may receive magnesium sulphate Recently, acetylsalicylic acid was replaced by sodium bicarbonate These tablets presented the same outward appearance as the genuine tablets, even as to the style of type used on the wrapper and the trademark of the manufacturer, also the glass tubes were of the same size, the outer capsule, with the name of the manufacturer stamped on it, and the label were close imitations of the original As certain quantities of these adulterated products have been sent to foreign countries, this word of warning may not be superfluous

"Diabetes Bacilli"

As the readers of THE JOURNAL doubtless know, the English bacteriologists Renshaw and Fairbrother recently *(British Medical Journal,* April 29, 1922) set up the hypothesis that the bacillus which was found by them in the stools of nine diabetics and which seemingly possessed the capacity to hydrolyze starch (named by them *Bacillus amyloclasticus-intestinalis)* may have an etiologic significance in diabetes—suggesting that diabetes is due to an intestinal infection Von Noorden makes the following critical comment

1 Withdrawal or restriction of carbohydrates, the essential nutrients for the growth of *Amylobacter* has played, for many years, an important part in the treatment of diabetes It has been repeatedly observed that restriction can be carried only to a certain degree and only in certain cases can it be pushed very far since otherwise the body becomes flooded with acetone bodies This clinical observation is thus sharply opposed to the theoretical conclusions reached by Renshaw and Fairbrother

2 Of the various foodstuffs containing carbohydrate in large quantities, the most marked sugar-forming effect, but at the same time one strongly opposing the formation of acetone, is found in sugar and finely milled flours, the carbohydrates of which are early absorbed into the blood from the small intestine, whereas the large intestine, which is the abode of intestinal bacteria receives only a very insignificant remnant from which no considerable quantities of acetone bodies can be formed On the other hand, a less marked sugar-forming effect with a greater tendency to acetone formation is observed in foods which contain carbohydrates in a not easily absorbable form for which reason a considerable portion of them reach the large intestine the seat of bacterial activity To this class belong graham bread and many of the vegetables In moderately severe cases of diabetes we can keep down the acetone by generous quantities of graham bread, although such bread offers rich nutrient material for *Amylobacter*

3 The digestion and assimilation of starch proceeds so rapidly that from the average amount of starch (about 80 gm) which diabetics consume daily, with excretion of acetone only a few grams enter the region of intestinal bacteria Since under especially favorable conditions, for 100 gm of starch only 9 gm of acetone is developed, it is evident that only a few decigrams can be formed for *Amylobacter* from the remnants However, in more severe types of diabetes the body excretes from 50 to 80 gm or even 100 gm of acetone bodies, daily, and the quantity commonly increases in proportion as the supply of starch is reduced The theory of the British investigators thus encounters unsolvable quantitative difficulties

4 In the presence of diarrhea, when starch, etc, reaches the region of intestinal bacterial flora much more quickly than usual the excretion by the diabetic of sugar and more particularly acetone will generally be lessened, whereas, according to the theory of the British writers, one would rather expect an increase On the other hand it seems very probable that in the acetone excretion of infants with diarrhea (without simultaneous excretion of sugar no diabetes) *Amylobacter* may possibly play a very important part If this should be confirmed, our English colleagues have made a very important discovery in the field of pediatrics

5 The prospects of getting at intestinal bacteria by means of disinfectants or by the introduction of antagonistic bacteria are very slight All the experiments conducted thus far some of which were carried out on a large scale in intestinal infections of various kinds, have failed of their purpose Even the Metchnikoff method, which seemed to have the best theoretical foundation (lactobacillin), accomplished only a very small part of what it was expected to accomplish, ten or twenty years ago Only the withdrawal of nutrients that favor the growth of definite groups of bacteria has proved of value and this is the basis of the modern therapy of intestinal catarrh But the method is no

applicable to *Amylobacter* since we must bear in mind that the withdrawal of carbohydrates favors the formation of acetone in diabetics As regards the statement of the writers that by mixing other bacteria with *Amylobacter* the latter's acetone-forming power is lessened, that is only what would naturally be expected In the large intestine, there are not only ferments (diastase) but also other bacteria that attack the starch-containing material and its cleavage products leaving for *Amylobacter* only a portion of the food that reaches that region

6 That infections may cause diabetes is generally assumed The causation is ascribed to a toxic injury of the pancreas with resulting impairment of its secretion Similar toxic injuries of other organs are associated with infectious diseases, for example, the kidneys, the heart muscle and the nerves

It becomes evident from the foregoing that von Noorden takes a very skeptical attitude toward the hypothesis of the English investigators

Marriages

GEORGE MARSHALL LYON, Huntington W Va, to Miss Virginia Berkley Sutherland of Washington, D C, at Elkins W Va, June 24

FRANCIS D ELLIS, formerly of Brooklyn to Miss Carolyn A Welles of Hartford, Conn, at Mahableshwur India, April 5

CLARENCE E RICE, Odell Neb to Miss Irene Dredla Crete, Neb, May 6

ARTHUR MAX KOHN Detroit to Miss Rose Simon of Chicago June 25

WALTER J CONNELL to Miss Lucy Riggs both of Dubuque Iowa June 22

HERMAN BICK to Miss Belle Bogen both of New York June 4

Deaths

Ernest Keys Cullen ⊕ Detroit, University of Toronto Faculty of Medicine Toronto, Canada, 1903, professor of gynecology, Detroit College of Medicine and Surgery, died July 5, from uncontrollable hemorrhage from ruptured varicose veins of the esophagus Dr Cullen a brother of Dr Thomas Cullen Baltimore was born in Belleville, Ontario May 14, 1878 Following his graduation he took three years graduate work at Johns Hopkins Hospital, Baltimore, and served his internship at the Toronto General Hospital He later entered Dr Howard A Kelly's service at the Johns Hopkins Hospital and afterward became resident gynecologist About 1912 he moved to Detroit and served as gynecologist to the City of Detroit Receiving Hospital the Harper Hospital and St Mary's Hospital Dr Cullen served during the World War with the Harper Hospital Unit, and was honorably discharged in 1919 with the rank of major He was a member of the Detroit Surgical Society and of the American Association of Pathologists and Bacteriologists

John Stanton Blackmar ⊕ Norwich, Conn, Columbia University College of Physicians and Surgeons New York, 1898, veteran of the Spanish-American War, captain in the M C U S Army during the World War, president and formerly secretary of the New London County Medical Association, member of the city council on the staff of the William W Backus Hospital died, June 24, aged 47, from angina pectoris

George E Hyde ⊕ Provo Utah University of California Medical School San Francisco 1895, superintendent of the State Mental Hospital at Provo since 1916, formerly president of the state board of health of Idaho for two years, and superintendent of the Idaho State Mental Hospital died, June 22 aged 57 at a hospital in Salt Lake City, following an appendectomy

Howell Shoener Zulick, Philadelphia, Medico-Chirurgical College of Philadelphia 1909, member of the Medical Society of the State of Pennsylvania, clinical professor of dermatology at the University of Pennsylvania lecturer on dermatology at Temple University was found dead in his chair, June 23 aged 39 from heart disease

Frederick Augustus Rand, Parrsboro N S, Medical Department of the University of the City of New York 1885 for thirty years county coroner and for six years chief magistrate of Parrsboro died April 25, aged 66, from heart disease following overexertion

Charles William Cullen, Cincinnati, Medical College of Ohio Cincinnati 1900 served in the M C U S Army, also a civil engineer superintendent of the Ohio Budget Commission member of the board of education, died recently in Denver aged 46

Charles Washington Bray ⊕ Portland, Me, College of Physicians and Surgeons in the City of New York 1874 formerly on the staffs of the Maine Eye and Ear Infirmary and the St Barnabas Hospital, died, June 22 aged 71, from heart disease

Charles Douglas ⊕ Detroit University of Toronto Faculty of Medicine Toronto Ont Can 1864 emeritus professor of pediatrics at the Detroit College of Medicine and Surgery, consulting physician at the Harper Hospital, died May 26 aged 78

Edward Dyer Ager, Antioch Calif Cooper Medical College San Francisco 1897 served for several years as surgeon in the M C U S Army and also during the world War died June 30 aged 46 at the Weimer Hospital at Martinez Calif

Sidney Worth, San Francisco New York Homeopathic Medical College New York 1874 formerly professor of pediatrics at Hahnemann Medical College of the Pacific San Francisco died May 20 aged 76 from heart disease

Robert Lloyd Williams ⊕ Statesan Wis Jefferson Medical College Philadelphia 1906 superintendent of the Wisconsin State Tuberculosis Sanatorium aged 41 was killed June 25 at Cleveland Ohio when struck by a street car

Mary Virginia McCune Rossa ⊕ Martinsburg W Va Woman's Medical College of Pennsylvania, Philadelphia 1895 proprietor and superintendent of the Shenandoah Valley Sanatorium, died suddenly May 15 aged 63

Irving I Sternman, Richmond Hill N Y, University and Bellevue Hospital Medical College New York 1921, on the

⊕ Indicates Fellow of the American Medical Association

staff of the St John's Hospital, Long Island City, died, June 28, aged 27, from bronchopneumonia

Harvey Hinchman Pettry ⊕ Colcord, W Va , Maryland Medical College, Baltimore, 1905, died, June 20, aged 53, from gunshot wounds received when a pistol carried in his holster accidently exploded

Thomas Caruth Dunn, Fountain Run, Ky , Medical Department, University of Tennessee, Nashville, 1889 member of the Kentucky State Medical Association, died, June 8, aged 62, from arteriosclerosis

George Wright, Glasgow, Scotland Trinity Medical College, Toronto Ont , Can , 1890 resident of Michigan, U S A , from 1898 to 1915, died, June 20, aged 65 from heart disease following influenza

William Jacob Haymaker, Export, Pa , Jefferson Medical College Philadelphia 1890, member of the Medical Society of the State of Pennsylvania, died, June 21, aged 57, following a long illness

Edward Payson Stimson ⊕ Tiverton, R I Dartmouth Medical School, Hanover, N H 1874, for several years medical examiner at Tiverton, died, July 5, aged 73, from heart disease

Charles H Ludwig, Chicago, Hahnemann Medical College and Hospital of Chicago 1875 practitioner in Chicago for more than forty years died, July 7, aged 71 from carcinoma of the rectum

John Smiele Turner, Monticello Ga , McGill University Faculty of Medicine Montreal, Canada, 1910, died June 6, aged 42, at Washington Park, Ga from chronic nephritis

William Edmund St Michael Raw, Hamilton Ont Can , M R C S England L R C P London and L S A London 1885, died, April 15, aged 62, following a long illness

Samuel Budd Page Knox, Santa Barbara, Calif , University of Pennsylvania Medical Department, Philadelphia, 1866, died suddenly June 30, aged 84, from heart disease

James Webster Shannon, San Diego Calif , Victoria University, Manchester, England, 1890, L R C P London and M R C S, England, 1890, died, June 19, aged 55

Calvin A Bonner, Dayton, Ohio, Medical College of Ohio Cincinnati, 1890, for several years city health officer, died June 23, aged 64, following a long illness

Robert Ormsby, Manhattan N Y , Medical Department of the University of the City of New York, 1876, died, June 9, at Flushing, aged 67, from heart disease

James H Proudlock, Danbury, Wis , College of Physicians and Surgeons, Keokuk, Iowa, 1887, died, May 24 aged 59, at the St Luke's Hospital, Duluth, Minn

David Winslow Hunt, Glendale, Calif , University of Michigan Medical School, Ann Arbor 1871, died, June 25, aged 76 from cerebral hemorrhage

George Sheldon Bingham, Hamilton, Ont , Victor University Medical Department, Toronto, Ont , Can , 1881, died, April 6, aged 64

Paul J Faber ⊕ Chicago, Chicago Medical College, 1890, died, July 7, aged 55 at the Augustana Hospital, from carcinoma of the liver

William Riley Jamison, Sacramento, Calif , California Medical College, San Francisco, 1895, died, June 30, at Watsonville, aged 64

James Harper, Gimlet, Ky , Barnes Medical College St Louis, 1899, formerly health officer of Elliott County , died April 1, aged 57

Harry Lee Courtright ⊕ Keokuk, Iowa, Keokuk Medical College, 1901, died, June 24, aged 45, following an operation

William H Raasch ⊕ Chicago, Chicago College of Medicine and Surgery, 1913, died, July 10, aged 35 from nephritis

Ralph H Williams, Bosworth, Mo , Missouri Medical College, St Louis, 1881, died, June 21 aged 63, from peritonitis

Edward Graeff West ⊕ Boston, Medical School of Harvard University, Boston, 1880, died, June 10, aged 66

George W Sellers, Mount Moriah, Mo , American Medical College St Louis, 1878, died, June 18, aged 80

John M Crenshaw, Liberty, S C , Atlanta Medical College, Atlanta Ga , 1882, died, June 2, aged 65

Charles Newton, Floral, Ark (licensed, Arkansas, 1903), died recently, aged 77, from cystitis

Gustav Jack, *Waco, Texas,* University of Zurich, Switzerland, 1884, died, June 14, aged 59

The Propaganda for Reform

IN THIS DEPARTMENT APPEAR REPORTS OF THE JOURNAL'S BUREAU OF INVESTIGATION OF THE COUNCIL ON PHARMACY AND CHEMISTRY AND OF THE ASSOCIATION LABORATORY, TOGETHER WITH OTHER GENERAL MATERIAL OF AN INFORMATIVE NATURE

MORE MISBRANDED NOSTRUMS

Abstracts of Recent Notices of Judgment Issued by the Bureau of Chemistry of the United States Department of Agriculture

Madam LeRoy's Regulative Pills—The LeRoy Chemical Co Baltimore, shipped in January, 1919, a quantity of "Madam LeRoy's Regulative Pills" which were misbranded The federal chemists reported that analysis showed the pills to contain aloes with traces of pennyroyal and tansy The product was labeled in part

A Menstrual Regulative ... an excellent formula for regulating the menstrual flow We have been selling them for many years with the *most satisfactory results* ... for suppressed or scanty menses ... will assist in restoring a normal condition '

These and similar claims were declared false and fraudulent and in May 1921, judgment of condemnation and forfeiture was entered and the court ordered that the product be destroyed—[*Notice of Judgment No 9854 issued Feb 21, 1922*]

Hooker's Cough and Croup Syrup—Charles B Kingsley, Northampton, Mass , shipped in August 1919, a quantity of Dr Hooker's Cough and Croup Syrup," which was misbranded The federal chemists reported that analysis showed the stuff to contain oil of anise, oil of wintergreen, alcohol, sugar, water, bloodroot and a balsam, probably tolu The preparation was falsely and fraudulently represented as an effective remedy for croup, catarrh, whooping cough, asthma incipient consumption and all diseases of the blood and lungs In June, 1921, Charles B Kingsley entered a plea of *nolo contendere* and the court ordered the information placed on file The government report does not explain why this individual was let off without even a fine—[*Notice of Judgment No 9851, issued Feb 21 1922*]

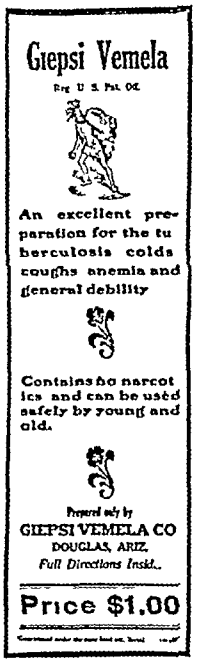
Naptholene—In May, 1920 Dr E E Sonnanstine, La Junta Colo shipped from Colorado to Missouri a quantity of Naptholene which was misbranded The Bureau of Chemistry reported that analysis showed the stuff to contain gasoline kerosene and a small quantity of resin of red pepper It was sold under the claim that it was a cure for rheumatism diphtheria, diabetes, appendicitis, toothache, all skin diseases, piles, Bright's disease and a number of other conditions These claims were declared false and fraudulent and in February 1921, judgment of condemnation and forfeiture was entered and the court ordered that the product be destroyed—[*Notice of Judgment No 9856, issued Feb 21, 1922*]

Homosan—The International Toilet Co Brooklyn, N Y, shipped during 1920 and 1921 from New York to Porto Rico a quantity of Homosan' which was misbranded The federal chemists reported that analysis showed it to consist of tablets containing a trace of strychnin The preparation was sold as a remedy for weakness of the testicles, atrophy of the prostate gland, spermatorrhea and impotence," and was recommended as an aphrodisiac These claims were declared false and fraudulent and, in May and August, respectively, 1921, judgments of condemnation and forfeiture were entered and the court ordered that the product be destroyed—[*Notice of Judgment No 9875, issued Feb 21, 1922*]

Haskin's Cough Medicine—The Haskin Medicine Co Binghamton, N Y, shipped in January, 1921, a quantity of 'Haskin's Cough Medicine" which was misbranded *Analysis by*

the Bureau of Chemistry showed that this preparation was a dark brown liquid carrying tar, chloroform sugar and water It was falsely and fraudulently recommended as a cure for all diseases of the throat and lungs, consumption, pneumonia, croup, asthma, etc In June, 1921, judgment of condemnation and forfeiture was entered and the court ordered that the product be destroyed —[*Notice of Judgment No 9877, issued Feb 21, 1922*]

Apollo Brand Sexual Pills—The S Pfeiffer Mfg Co, St Louis, Mo, shipped in November, 1920, a quantity of "Apollo Brand Sexual Pills' which were misbranded The Bureau of Chemistry reported that analysis showed these pills to contain extracts of nux vomica and damiana and phosphorus The aphrodisiac effect claimed by inference for this product in the name was declared by the government to be false and fraudulent and in August, 1921, judgment of condemnation and forfeiture was entered and the court ordered that the product be destroyed —[*Notice of Judgment No 9894, issued Feb 21, 1922*]



Giepsi Vemela—The Giepsi Vemela Co, Douglas Ariz shipped a quantity of this product in February, 1921, which the federal authorities charge was misbranded The Bureau of Chemistry reported that analysis showed the preparation to consist of vegetable extractives, sugar and water The stuff was falsely and fraudulently recommended as an effective treatment and cure for tuberculosis, sore throat, weak stomach tumors, ulcers, buboes and various other conditions In October, 1921, judgment of condemnation and forfeiture was entered and the court ordered that the product be destroyed —[*Notice of Judgment No 10036, issued May, 1922*]

McMullin's Tonic—In the early part of 1921 the Tilden McMullin Co, Sedalia, Mo, shipped from Missouri to Colorado a quantity of 'McMullin's Tonic' which was misbranded The Bureau of Chemistry reported that analysis showed this stuff to contain alcohol glycerin iodids carbolic acid and water The stuff was falsely and fraudulently labeled as a relief for consumption asthma, catarrh, bronchitis, etc In August, 1921, judgment of condemnation and forfeiture was entered and the court ordered that the product be destroyed —[*Notice of Judgment No 9886, issued Feb 21, 1922*]

Dupree's French Specific Pills—The United Drug Exchange, New York City shipped in October, 1920 and May, 1921 a quantity of 'Prof Dupree's French Specific Pills" which were misbranded The chemists of the Bureau of Chemistry reported that analysis showed the product to contain aloes iron sulphate, and a trace of alkaloids with indications of cotton-root bark and tansy The stuff was sold 'For use in the suppression of irregularities of the menses" and false and fraudulent claims regarding the therapeutic effects were made for it In August, 1921 judgment of condemnation and forfeiture was entered and the court ordered that the product be destroyed —[*Notice of Judgment No 9888, issued Feb 21 1922*]

Shores Lung Balsam and Shores Mountain Oil Liniment—In March 1920 the Shores-Mueller Co Cedar Rapids Iowa, shipped a quantity of Shores Lung Balsam" and "Shores Mountain Oil Liniment both of which were misbranded The federal chemists reported that the 'Lung Balsam' contained pine tar, ammonium chlorid a salicylate chloroform, glycerin, sugar and water It was falsely and fraudulently represented as an effective treatment and cure for sore lungs, bronchitis, whooping cough, croup and throat trouble

The "Mountain Oil Liniment' according to the federal chemists, contained cajeput wintergreen, sassafras, cedar oils camphor, ammonia, borax, washing soda, plant extractives, capsicum oleoresin, alcohol and water This was falsely and fraudulently represented as an effective treatment and cure for colds, cramps, colic, cholera morbus, diarrhea, rheumatism indigestion, sore throat, mumps and other things In addition to these false and fraudulent claims the product was further misbranded in that the amount of alcohol contained therein was not correctly stated In October 1921, a plea of guilty was entered on behalf of the Shores-Mueller Co and the court imposed a fine of $50 and costs —[*Notice of Judgment No 10044, issued May 1922*]

Montauk Star Brand Pills—A quantity of "Montauk Star Brand Pills,' offered for sale in the District of Columbia in July 1921 was charged by the federal officials with being misbranded The Bureau of Chemistry reported that analysis showed the pills to contain iron sulphate, aloes and a trace of strychnin The preparation was sold under the claim that it was For use in the suppression of irregularities of the menses' These and similar claims were declared false and fraudulent and in October 1921, judgment of condemnation and forfeiture was entered and the court ordered that the product be destroyed —[*Notice of Judgment No 9908, issued March 6 1922*]

Princess Brand Pennyroyal, Tansy and Cotton Root Bark Compound Pills—These pills were being offered for sale in Washington D C in July 1921 ,The government chemists reported that analysis showed the pills to contain aloes They were falsely and fraudulently labeled as "A Safe, Reliable Powerful Yet Harmless, Emmenagogue' In October 1921 judgment of condemnation and forfeiture was entered and the court ordered that the product be destroyed —[*Notice of Judgment No 9919, issued March 6 1922*]

Shores Sarsaparilla—In October, 1920 the Shores-Mueller Co Cedar Rapids Iowa shipped a quantity of this product which was misbranded The federal chemists reported that Shores Sarsaparilla contained extracts of plant drugs, including a laxative a salicylate a small amount of ammonium chlorid a trace of alcohol, glycerin and water The stuff was falsely and fraudulently represented as an effective cure for catarrh rheumatism boils blood and skin diseases, bad breath eczema general debility, female weakness etc In October 1921 a plea of guilty was entered by the Shores-Mueller Co and the concern was fined $20 and costs —[*Notice of Judgment No 10048, issued May, 1922*]

Correspondence

A DEFENSE OF GROUP MEDICINE

To the Editor —The communication by Dr Wilson on the disadvantages and limitations of clinic or group medicine in THE JOURNAL June 24 provoked in me a decided reaction Much of the criticism he offered is true but as he said can be applied with equal justice to the consultant and to the general practitioner Other criticisms of group practice need only to be recognized to be obviated A properly organized and managed modern clinic in a small city is far from being a "soulless corporation' Its members are conscientious physicians with as definite a clientele as the so called family physician What is the evidence that the average consultant or even general practitioner takes into account the individual's psychologic reaction any more definitely than does a member of a small group in a small city?

The question whether specialists in the large cities and medical centers should unite into groups is a debatable one In cities ranging from 5 000 to 50 000 inhabitants however—and there are 1 275 of these in the United States—the situa-

tion is entirely different In these smaller communities it is almost impossible for one to confine oneself strictly to a specialty unless one is in a group or in some sort of partnership General practitioners are everywhere clipping turbinates, removing tonsils, doing cesarean sections and performing every minor and major operation they think they can get away with With the optometrists competing strongly for the refraction work it is rare to find even an eye, ear, nose and throat specialist in the smaller cities who is not also engaging in general practice It is manifestly impossible for an internist a urologist, a pediatrician, a neurologist, a radiologist or even a general surgeon to make a living in most of these cities Patients with conditions requiring expert attention are thus often either improperly treated, or are forced to make long, expensive journeys to specialists in distant cities

On the other hand it is possible, and has been shown to be feasible for a group of physicians to unite and confine themselves strictly to their specialties, and bring scientific medicine to these smaller communities A well-organized clinic has a complete library and a well equipped laboratory with roentgen ray and other diagnostic apparatus which it is almost impossible for one man to own or operate Scientific clinical and research work can be done at such a clinic as well as at the leading medical centers If even 1,000 of these cities should contain such a clinic think of the rapid advance that would be made in the practical application of scientific medicine

The concept of the health center elaborated by Billings and others is in many respects ideal, but like all ideals which require public cooperation is difficult of realization In addition, politics is likely to interfere at the most inopportune time, and in a day destroy or vitiate years of labor Furthermore, no room is made in this regime for the true specialist In fact, the temptation for the general practitioner to attempt everything would be even greater than at present It is generally recognized that municipal, county and private hospitals with the so-called open door policy of admitting all licensed practitioners, regular or irregular, to their wards and operating rooms have promoted the growth of the present day 'specialist in everything The case of the community hospital recently cited in THE JOURNAL in which all of the practicing physicians in the community were on the staff, and a rotating service was maintained whereby each physician was in charge of the surgical ward for a certain period every two years, and again was in charge of the medical ward for a like period, illustrates the pernicious possibilities of this plan

I would ask this question Given a community that can support five physicians is it better for each to attempt to do everything, or for the five to combine and each confine himself to the specialty for which he is best fitted?

JOHN W VISHER, M D, Twin Falls, Idaho

THE EDITIO MAGNA OF VESALIUS

To the Editor —Recently I had the fortune to secure a copy of 'Editio Magna" of Vesalius the 1543, Operinus, Basle Edition I believe the copy, which I have, is the finest in this country It belonged to Lancisi, and was given with his other books to the Library of The Holy Ghost in Rome in 1714 After that time the library was called 'The Bibliotecn Lancisiana," and the books were dispersed at the time of the Napoleonic Invasion of Italy I am anxious to communicate with others, who own copies of this edition, in order that a list and location of these books may be recorded

SPINAL AND CISTERN PUNCTURE IN DIAGNOSIS AND TREATMENT OF INTRACRANIAL HEMORRHAGE

To the Editor —Please describe the fundamental principles of the value of spinal and cistern puncture in the diagnosis and therapeutics of intracranial hemorrhage mentioned in an abstract (THE JOURNAL, May 20 p 1570)

J G BAJANDAS M D Coamo, P R

ANSWER —Spinal puncture has long been used in both the diagnosis and treatment of meningeal hemorrhage Obviously, no blood will find its way into the cerebrospinal fluid unless the hemorrhage is primarily meningeal or ventricular, or if it ruptures into the subarachnoid space or a ventricle If the hemorrhage is recent, red corpuscles will be found, if old, the fluid will be more or less straw-colored on account of the hemoglobin or its derivatives dissolved in it With an intracranial hemorrhage blood will be found earlier and in greater quantity by cistern puncture than by lumbar puncture The therapeutic value of lumbar puncture in intracranial hemorrhage especially of the traumatic variety, has been amply testified to Thus a French army surgeon, F Albert (*Lyon chirurgical* **15** 328 [March-April] 1918) said Lumbar puncture should have a place of honor in all craniocerebral surgical establishments In all doubtful cases of skull fracture or meningeal hemorrhage it settles the diagnosis All cases of concussion and cerebral hypertension are accompanied by hypersecretion of cerebrospinal fluid Lumbar puncture is the treatment, counteracting at one time both cause and effect It is the only efficient treatment of basal fracture If this observer had been familiar with cistern puncture even the French language probably would hardly have sufficed to express his enthusiasm

Cistern puncture is rather new, and so far has principally been used in cases of spinal subarachnoid block and for injections of arsphenamized serum in paresis The case reported by Ruggles and Wyatt (*Boston M & S J* **186** 572 [April 27] 1922), to which our correspondent refers, demonstrates that bloody fluid may be readily obtained by cistern puncture in a case of cerebral hemorrhage when for some reason or other lumbar puncture gives a dry tap" That no block existed in this case was shown by the fact that salt solution injected through the spinal puncture needle caused the cistern pressure to rise To our knowledge, this is the only case of hemorrhage reported in which the combined puncture has been used, and with apparent success, for the purpose of flushing out the cistern and subarachnoid space, but it has been used with benefit in cases of meningitis

SACHS ANTIGEN

To the Editor —In Queries and Minor Notes it was stated in reply to Dr Watson's question (THE JOURNAL May 20 1922 p 1558) that in Dold's test a cholesterolized antigen is used prepared according to Sachs method Will you describe this method and also how to secure this antigen?

GABRIEL RIGAU M D Yauco Porto Rico

ANSWER —The antigen is thus prepared A normal beef heart is freed from fat, pericardium and large blood vessels, and then ground up fine in a meat chopper The minced heart muscle is now mixed with five volumes of 95 per cent alcohol, and shaken vigorously in a shaking machine four or five hours After standing at room temperature over night, it is filtered through ordinary filter paper, and placed in the icebox for at least two days, at the end of this time it is filtered again through filter paper to remove any precipitate that formed while in the icebox It is now ready, and is stored at room temperature Before use in the test it must be diluted with two volumes of alcohol, cholesterinized by the addition of from 0 045 to 0 06 per cent of a 1 per cent alcoholic solution of cholesterol, and titrated against a known standard antigen

The Sachs-Georgi test for syphilis was discussed by Parker and Haigh in the *Archives of Dermatology and Syphilology* 4 67 (July) 1921

OSGOOD SCHLATTER DISEASE

To the Editor—Please describe the Osgood Schlatter disease of the tuberosity of the tibia

MARK HOUSTON, M D Urbana Ohio

ANSWER—Osgood-Schlatter disease (Schlatter's disease, Schlatter's spram) is a condition of partial functional incapacity, due to thickening separation or partial separation of the tibial tuberosity The etiology and pathology of the disease are still obscure Some think that the condition is a dystrophy, others that it is due to inflammation Connell believes that the disease is a purely traumatic condition, most common in those under 17 years of age, imperfect union of the tibial tubercles being a predisposing factor Since many cases are bilateral, and other muscular and ligamentous insertions may show periosteal thickening, DaCosta believes that the condition is probably systemic Müller says that Schlatter's disease is a symptom of a systemic pathologic condition that manifests itself in a tendency to spontaneous separation of the epiphyses, and infractions, and that it is connected with late rachitis

ADMINISTRATION OF TYPHOID VACCINE

To the Editor—1 It has been my custom to advise persons who have had typhoid fever not to take prophylactic typhoid vaccination on the assumption that they had as complete active immunity as they could develop I would appreciate information as to whether I am following the most accepted ideas on the subject

2 I would also like to know to what extent it is considered best to decrease the dosage of vaccine for little children and whether it is good practice not to give it at all to children under 2 years of age

SUBSCRIBER

ANSWER.—1 The immunity acquired by typhoid patients is usually good enough to make vaccination superfluous, provided the diagnosis has been correct If the vaccine is to be employed it is better to start with a small dosage

2 Chantemesse recommends that children be given four vaccinations with doses proportioned to the weight of the child For instance, a child weighing 35 kg should receive half the dose a child weighing 18 kg one quarter of the dose for adults The age under 2 years is not a contraindication but in these children the disease is comparatively rare and not severe

Medical Education, Registration and Hospital Service

COMING EXAMINATIONS

SOUTH DAKOTA Waubay July 18 Director Dr H R Kenaston Bonesteel

Wisconsin Reciprocity Report

Dr John M Dodd, secretary, Wisconsin State Board of Medical Examiners reports that at the special meeting held at Milwaukee, April 12, 1922, eight candidates were licensed by reciprocity Four candidates were licensed on government credentials The following colleges were represented

College	LICENSED BY RECIPROCITY	Year Grad	Reciprocity with
Loyola University		(1921)	Illinois
Northwestern University	(1910)	(1921)	Illinois
Rush Medical College	(1921 2)		Illinois
University of Michigan Medical School		(1906)	Michigan
University of Minnesota		(1898)	Minnesota
Columbia University		(1919)	New York

College	ENDORSEMENT OF CREDENTIALS	Year Grad	Endorsement with
Hahnemann Med College and Hospital of Chicago		(1915)	U S Army
University of Illinois		(1913 2)	U S Army
Medical College of Virginia		(1917)	U S Army

District of Columbia January Examination

Dr Edgar P Copeland secretary District of Columbia Board of Medical Supervisors reports the oral and written examination held at Washington Jan 10, 1922 The examination covered 8 subjects and included 80 questions An average of 75 per cent was required to pass Of the 10 candidates examined 7 passed and 3 failed Three candidates were licensed by reciprocity The following colleges were represented

College	PASSED			Year Grad	Per Cent
Howard University	(1920)	77 2	85 7	(1921)	84 8
Harvard University				(1919)	93 6
University Med College of Kansas City	(1910)	80 7		(1921)	82 1 89 5

College	FAILED			Year Grad	Per Cent
Howard University	(1920)	68 3		(1921)	74 6
University of Minnesota				(1920)	74

College	LICENSED BY RECIPROCITY	Year Grad	Reciprocity with
Illinois Medical College		(1900)	Mississippi
Jefferson Medical College		(1916)	Penna
Fort Worth School of Medicine		(1901)	Texas

Hawaii April Examination

Dr Guy C Milnor, secretary, *Hawaii Board of Medical* Examiners reports the written examination held at Honolulu April 11 13, 1922 The examination covered 11 subjects and included 55 questions An average of 75 per cent was required to pass Of the 3 candidates examined, 1 passed and 2 failed The following colleges were represented

College	PASSED	Year Grad	Per Cent
John A Creighton Medical College		(1917)	75

College	FAILED	Year Grad	Per Cent
College of Physicians and Surgeons San Francisco		(1901)	40
Atlanta School of Medicine		(1913)	70

Oklahoma April Examination

Dr J M Byrum, secretary, Oklahoma State Board of Medical Examiners, reports the written examination held at Oklahoma City April 11-12, 1922 The examination covered 12 subjects and included 120 questions An average of 75 per cent was required to pass Of the 4 candidates examined 3 passed and 1 failed Two candidates were granted reregistration licenses, and one candidate received a duplicate license Thirteen candidates were licensed by reciprocity One candidate was licensed on Navy credentials The following colleges were represented

College	PASSED	Year Grad	Per Cent
Bennett Medical College		(1913)	78
Tulane University		(1919)	83
University of West Tennessee		(1920)	75

College	FAILED	Year Grad	Per Cent
Meharry Medical College		(1921)	64

College	LICENSED BY RECIPROCITY	Year Grad	Reciprocity with
University of Arkansas		(1918)	Arkansas
Atlanta College of Physicians and Surgeons		(1913)	Texas
Atlanta Medical College		(1913)	Georgia
Louisville Hospital Medical College		(1900)	Arkansas
Tulane University	(1918) Texas	(1919)	Missouri
Ensworth Medical College	(1908) Kansas	(1910)	Nebraska
St Louis College of Physicians and Surgeons		(1911)	Arkansas
University Medical College of Kansas City		(1904)	Utah
Miami Medical College		(1899)	W Virginia
University of Tennessee	(1913)	(1914)	Arkansas

Northwestern University		(1917)	U S Navy

The Drugless Cults in Germany—The *Munchener medizinische Wochenschrift* warns that the organized irregular practitioners have founded the Verband fur Volksheilkunde which is circulating petitions protesting against the proposed notification of venereal disease and compulsory treatment claiming that the public is being enslaved etc The charlatans are making every effort to combat this dreaded regulation as it will deprive them of their most fertile field of work and they are carrying on this agitation to bring pressure to bear on the legislators The communistic party in the reichstag is warning against the dangerous and selfseeking aims of the petition and is urging people not to sign it and the German Antiquackery Society is appealing to the medical and lay press to expose the true motive of the petition

Book Notices

SURGICAL AND GYNÆCOLOGICAL NURSING By Edward Mason Parker M D F A C S Surgeon to Providence Hospital, Washington D C, and Scott Dudley Breckinridge M D F A C S, Gynecologist to St Joseph s Hospital Lexington Kentucky Second edition Cloth Price $3 net Pp 425 with 134 illustrations Philadelphia J B Lippincott Company 1921

This book consists of six parts The first part is biologic, and summarizes bacteriology and wound infection The second part deals with surgical pathology and surgical nursing The third covers minor technic in surgical nursing, application of dressings and bandages, and an outline of the Carrel-Dakin technic In the fourth part the patient is considered, postures and the details of preparation and of observation are described The fifth part describes the operating room its contents personnel and technic There is a complete collection of photographs of instruments designed to enable the nurse to identify them The sixth is supplementary, the gynecology dispensary, emergencies, and an epitome of surgical and of gynecologic conditions are detailed The work is written in interesting style, it is accurate in all essentials, and covers in small space a wide field in a way sufficiently complete to supply the nurse not only with basic principles, but also with details

DER BALKEN EINE ANATOMISCH PHYSIOPATHOLOGISCHE UND KLINISCHE STUDIE Von Dr G Mingazzini O Professor an der Klinik fur Nervenkrankheiten der Kgl Universitat Rom Paper 160 marks Pp 212 with 84 illustrations Berlin Julius Springer 1922

This is No 28 of the neurologic monographs edited by Foerster and Wilmanns It is an ideal monograph, giving to the reader a clear and authoritative account of everything known about the anatomy embryology, physiology and pathology of the corpus callosum The author has devoted a great deal of his recognized investigative ability to the study of this important and conspicuous, yet rather neglected and mysterious, portion of the brain, which shares with the pineal gland the honor of having been considered several hundred years ago as the seat of the soul The most common lesions giving rise to clinical syndromes are complete or partial defect, tumors, vascular lesions, and a peculiar type of degeneration encountered in alcoholics

ON MODERN METHODS OF TREATING FRACTURES INCLUDING THE JACKSONIAN PRIZE ESSAY ON BONE GRAFTING By Ernest W Hey Groves M S M D B Sc Surgeon to the Bristol General Hospital Second edition Cloth Price $8 Pp 435 with 296 illustrations New York William Wood & Co 1922

The general lack among clinicians of an accurate conception of pathologic changes in the bones, the difference of opinion as to treatment still existing among competent surgeons, and the all too large percentage of bad results following the treatment of fractures serve to make such a monograph as this a valuable contribution to bone literature Bone" literature rather than "fracture" literature is employed because of the broadness of the scope of the work The first part is devoted to the general principles of massage, mobilization and extension The greater part of the remainder is devoted to operative methods of treatment and the experimental basis of this treatment There is a very good summary of the more important contributions to the literature of experimental research on bone The author has added the results of a considerable amount of experimental work of his own, and gives a clear-cut presentation of the status of bone regeneration and the living graft The only criticism that may be offered, if it may be so designated, is the apparent inclination of the author to the operative rather than to the nonoperative side This, of course, we recognize as less of a failing when practiced by a competent man Nevertheless, for the great majority who are not competent, this is bad teaching, because bad results following operative exposure of a fracture are far more disastrous than when such exposure has not been made and because bone surgery is technically difficult Sepsis, against which every writer on the subject warns, is far more likely to occur in an open fracture than in a laparotomy wound Many may contest the statement of the author that such sepsis is "probably postoperative in its origin" Nevertheless, the text is clearly the work of a master, it is interestingly written, and the illustrations are many and beautiful

THE STOMACH AND ABDOMEN FROM THE PHYSICIAN S STANDPOINT By William Russell M D LL D Consulting Physician Royal Infirmary Edinburgh Cloth Price $4 Pp 329 with 35 illustrations New York William Wood & Company 1921

At a time when many are looking for short cuts to diagnosis and the burden of proof is laid at the door of the clinical or roentgen-ray laboratories, it is refreshing to have brought back to us in a clear manner and in delightful and simple English the real value that is obtained in carefully eliciting a history and as carefully making a physical examination Dr Russell believes it to be the duty of the physician, as distinguished from the surgeon, to assume the responsibility of diagnosis He decries the readiness with which exploratory operations are resorted to, and considers them the bane of differential diagnosis A rather novel explanation of gastric disturbances is given All center about gastric chemism Disordered or pathologic states are divided into two classes, determined by increased or decreased hydrochloric acid secretion These conditions are considered as clinical entities Thus, the author speaks of an acid dyscrasia of the stomach, of which peptic ulcer is a complication or sequel In fact, the failure to recognize this dyscrasia is the reason for the diagnosis of ulcer being made so frequently Numerous carefully elicited histories which, in the light of our present knowledge, assisted by roentgen ray examination, would lead to a diagnosis of ulcer, in the author s opinion, point to simple hyperchlorhydria Only in the later chapters of the book is the prominence given to roentgen-ray examination that it deserves Ideas are submitted which seem hardly in accord with modern views, such as sudden relaxation of spasm of the pylorus as a cause of gastric cramps There are scarcely any references to recent work in gastric physiology There are chapters on diseases of the stomach and intestines, spleen, liver, jaundice and the kidney Differential diagnosis is considered very carefully Many citations of history records from Dr Russell's personal experience are given To each are appended paragraphs on diagnosis and treatment The impression gained is that this little volume would prove to be of considerably more value to the beginner than to one with the mature judgment of years of practice

LEHRBUCH DER SPEZIELLEN PSYCHIATRIE FÜR STUDIERENDE UND AERZTE Von Professor Dr Alexander Pilcz Sixth edition Paper Price 80 marks Pp 315 Leipsic Franz Deuticke 1922

Written specifically for students and practitioners, this textbook is limited strictly to a description of the clinical varieties of mental disease and defect General symptomatology, pathogenesis and dynamic psychology have been intentionally omitted, on the assumption that they are of no practical value, and are of interest only to the specialist Whatever one may think of this view, there can be no hesitation in asserting that the task undertaken has been admirably carried out The descriptions are concise, and yet extraordinarily full, the language and style are simple, but vividly real, and there is an entire absence of dry monotonous technicality, which so often makes this subject the bane of the student's existence Few headings are used, each named disorder being considered under symptoms psychic and somatic, course, prognosis, differential diagnosis, etiology, and therapy Pathologic anatomy is described briefly when anything is known Treatment is accorded perhaps more than its usual quota of space, a special chapter being added on the use of drugs, and is thoroughly up to date, with the exception that there is no mention of occupational therapy or psychotherapy War experiences are quoted freely, and there is a short chapter on hypnosis The descriptions of the psychopathic states, especially "moral insanity," are strikingly good, and both here and elsewhere the medicolegal considerations are eminently practical and useful

Medicolegal

Negligent Treatment of Fracture

(Petefish v Morrison (Kan) 205 Pac R 651)

The Supreme Court of Kansas, in affirming a judgment for damages in favor of the plaintiff, but without stating the amount of the judgment, says that the plaintiff's right leg was broken near the ankle, and the defendant was called to treat the injury He dressed the broken limb, braced it with a splint, and propped the foot straight forward with a pillow The weight of the foot, however, caused it to turn outward, and in that position the fracture healed, so that thereafter as the plaintiff walked her right foot turned outward at an angle of nearly 90 degrees An orthopedic surgeon testified that it is elementary in setting fractures that the limb must be placed in a normal position, immobilized and held firmly by some method in its normal position until the bones have an opportunity to mend, that if the foot was rotated outward that was sufficient notice that the foot should be put back in a normal position and held there, independently of whether a roentgenogram was available or not Many witnesses testified for the plaintiff that this precaution to keep the foot in position was not taken, and that it was permitted to lie over and outward to the right The defendant s visits to his patient continued off and on for about three weeks before he discovered that her foot was everted, by which time the cartilaginous substance had so far formed that the foot could only have been straightened by more pain and suffering, while the record showed that the plaintiff had certainly borne enough of that, partly owing to the wrong position of her foot while the fracture was healing For the defendant, there was evidence that the foot was correctly placed and the fracture properly treated, and it was argued for him that he undertook to render limited services only, that he told the plaintiff she should go to a hospital where a roentgenogram of her injury could be taken and where she would receive more attention, that her accident occurred during an epidemic of influenza, that he had so many patients he was going night and day, sleeping only three or four hours in the twenty-four, at the time, and that the eversion of the foot was caused by the plaintiff's own negligence But the disputed facts were all disposed of by the jury's verdict, and, no error being found in the record of the trial, the judgment for the plaintiff was affirmed

Evidence Admissible to Show Defendant was a Moron

(People v Joyce (N Y) 134 N E R 836)

The Court of Appeals of New York in reversing a judgment of conviction and ordering a new trial in this homicide case, says that a number of officers and detectives of the police force testified as witnesses for the prosecution as to statements alleged to have been made by the defendant Counsel for the defendant, in his opening of the case to the jury, stated that he would show that the defendant had a mind of a youth of 9 or 10 years The district attorney objected on the ground that it was not a matter of defense in the case as to the condition of the defendant s mind, and the trial judge said, "He has not claimed to be insane" Counsel then went on to state that it would be proved by competent evidence that the defendant's mentality was such that he would yield if any one who had a stronger mind insisted talked well pleaded or threatened But counsel having thus assured the jury that he would establish that the defendant had the mind of a child from which he would argue that, even assuming that the defendant made the statements attributed to him such statements were the result of suggestion and lack of comprehension on his part of what he was stating or the result of an illusion that he was a hero was denied the privilege of making any proof of the defendant's mental condition A specialist in nervous and mental diseases was called as a witness Having testified as to his experience, and that he had examined the defendant in the county jail he was asked to tell the condition in which he found the defendant The district attorney objected to the question, and the judge stated that he did not understand the theory, that there was no defense of insanity interposed Counsel then explained that he intended to prove by the physician that the defendant's mind was such that judging from the test he had the mind of a boy between the ages of 10 and 12 years, and that, this being so, his mind was easily influenced by people who had stronger minds, and that by beating him and talking to him, the officers would be able to get his mind in such a condition that he would not know what he was saying, or, if he did say something it would not be true The judge's answer was that if the defendant did not positively assert that he made no such statement to the officers at all, if he admitted that he had told the officers these things, and that he was either tweedled, tracked, or tricked into it, that would be relevant testimony But he had said that he did not make any such statement, and the only theory possible was that the testimony which he himself gave was false, which the court would not want to assume However, the court of appeals holds that the trial justice was in error in suggesting that the defendant was required to file a special plea of insanity or lack of mentality as a prerequisite to the introduction of evidence of insanity or lack of mentality If the defendant was what is known in medical jurisprudence as moron, that is, one whose intellectual development proceeds normally up to about the eighth year of age, and then arrested, never exceeds that of a normal child of about 12 years evidence of such fact was material for consideration by the jury The fact that the defendant denied the statements testified to by the officers was not a legitimate reason for a rejection of the evidence Such denial would not bar him from offering such proof or his counsel from arguing that in the event he made such statements he was not of sufficient mentality to understand what he was stating or that his mind was controlled by a superior force or intellect A question put to the defendant's mother as to whether he had a fall when he was a little boy was likewise competent, and an answer thereto should have been permitted

Summary Quarantine and the Writ of Habeas Corpus

(Ex parte Casells (Mont) 204 Pac R 564)

This was an application in chambers before Chief Justice Brantly of the Supreme Court of Montana, for a writ of habeas corpus In discharging the writ and remanding the complainant to the custody of the sheriff, the chief justice says that there is perhaps, no authority to be found at this late day which denies that the legislature, under its police power, may enact laws authorizing the establishment of quarantine regulations and requiring the detention of persons affected with contagious diseases dangerous to the public health, without resort to a preliminary judicial proceeding to determine the character of the disease and the facts constituting the danger to public health Under the Montana statute involved in this case the proper health officer may issue his warrant directing the arrest, without notice, of any person reasonably suspected of having a communicable disease and his detention for the time being and until the existence and character of the disease can be determined, and in case his course of conduct or condition is such in the judgment of the health officer, as to render it necessary in order to protect the public health, he may isolate the person in question until he recovers from the disease or until he may be released without further danger to the public If however after his arrest, the person challenges the right of the authorities to continue his detention he is entitled to have it legally inquired into on habeas corpus

The existence of the power of the health officer to detain any one rests on the existence of the facts making such detention necessary The law does not deprive any citizen of the right to be heard on this question, but he is not entitled to a hearing in the first instance that is to say, before he is taken for quarantine The fourteenth amendment to the constitution of the United States and the sections of the constitution of the state of Montana requiring due process of law have no application to this class of cases Counsel for the state insisted that the finding of the county health officer in such a case, declaring that the detained citizen is

afflicted with a contagious disease, and is therefore dangerous to the public health, is conclusive and not subject to review by the courts There is some conflict of authority on this subject, but the great weight of it supports the rule stated the law does not tolerate the arrest and detention of any citizen without the right to challenge the existence of the facts on which he is held

The complainant in this case was held by the sheriff under an order of the health officer of the city and county of Missoula, made under the quarantine regulations established by the state board of health, under Chapter 106 of the Laws of the Sixteenth Legislative Assembly, on the ground that according to the information of the health officer, she was affected with gonorrhea a disease declared by the statute to be contagious communicable and therefore dangerous to the public health She applied for a writ of habeas corpus to obtain her release on the grounds that she was not granted a judicial hearing prior to the time she was taken and detained by the sheriff and that the facts did not exist showing that she was affected with the disease and so conducted herself as to be dangerous to the public health The facts introduced at the hearing established clearly that she was affected with gonorrhea This was ascertained by scientific means by the bacteriologist employed by the state board of health, on the application of the health officer The only uncertainty was whether, in the condition she was in, she would, in fact, be dangerous to the health of the community in which she lived if she were allowed to go at large The testimony was not satisfactory, but it did disclose circumstances which justified the inference that she, within a comparatively short time prior to her arrest, had been plying her trade of prostitute, and, on all the evidence, the conclusion is reached that the health officer was justified in directing her detention until she should become cured or until she might be safely allowed to go at large

Indictable Prescribing of Narcotics

(United States Behrman (U S) 42 Sup Ct R 301)

The Supreme Court of the United States, reversing a judgment sustaining a demurrer to an indictment of the defendant a physician registered under the Harrison Narcotic Law says that the law contains an exception to the effect that it shall not apply to the dispensing or distribution of such drugs to a patient by a registered physician in the course of his professional practice only nor to the sale dispensing or distribution of the drugs by a dealer to a consumer under a written prescription by a registered physician The rule applicable to such statutes is that it is enough to charge facts sufficient to show that the accused is not within the exception The district judge who heard this case was of the opinion that prescriptions in the regular course of practice did not include the indiscriminate doling out of narcotics in such quantity to addicts as charged in the indictment, but out of deference to what he deemed to be the view of a local district judge in another case announced his willingness to follow such opinion until the question could be passed on by this court and sustained the demurrer In this court's opinion, the district judge who heard the case was right in his conclusion and should have overruled the demurrer

Former decisions of this court have held that the purpose of the exception is to confine the distribution of these drugs to the regular and lawful course of professional practice and that not everything called a prescription is necessarily such It may be admitted that to prescribe a single dose or even a number of doses may not bring a physician within the penalties of the act, but what was here charged was that the defendant physician, by means of prescriptions, had enabled one, known by him to be an addict to obtain from a pharmacist the enormous number of doses contained in 150 grains of heroin, 360 grains of morphin and 210 grains of cocain Undoubtedly, doses may be varied to suit different cases as determined by the judgment of a physician But the quantities named in the indictment were charged to have been intrusted to a person known by the physician to be an addict, without restraint on him in its administration or disposition by anything more than his own weakened and perverted will Such so-called prescriptions could only result in the gratification of a diseased appetite for these pernicious drugs, or result in an unlawful parting with them to others, in violation of the act as heretofore interpreted in this court

Test When Defense Is Insanity—Nonexpert Opinions

(Feree v Commonwealth (Ky) 236 S W R 246)

The Court of Appeals of Kentucky, in affirming a judgment of conviction of defendant Feree, says that he was charged with wilful murder, and the defense was made that he was insane at the time of the shooting But no rule is more generally acknowledged, nor more fully sustained by reason, than the one which presumes every person to be of sound mind until the contrary is shown by a preponderance of the evidence One who enters a plea of insanity to a criminal charge must show by a preponderance of the evidence that his mind was so far gone so diseased and unsound that he did not know the consequences of his act, nor realize that he was doing wrong at the time of the act of which complaint is made It is the theory of some students of physiology *and assented to by many alienists, that most persons* have insane delusions on one or more subjects although they are of sound mind on all other subjects and may be good business people, industrial workers or leaders of thought, and this may or may not be true This court thinks, however that the true test in criminal cases is Did the defendant at the time he struck the blow or fired the shot which injured or killed another know or realize the consequences of his act? If he did, then he is guilty both at law and in morals If he did not know and was not able to realize the consequences of his act, then he was not responsible therefor either in law or morals Even though one may be possessed of insane delusions on one or more subjects he is liable for his criminal acts, if at the time he performs them he knows and realizes that he is doing wrong Cases are not infrequent in which one is sane part of the time and insane at other times If such a one commit a crime during his lucid intervals, he is as responsible as if he had never suffered from dementia The defendant, Feree, may have been insane, or so unbalanced mentally at the time of his breakdown some years before the killing with which he was charged in this case, that he would not have been responsible for his criminal act, but if he afterward recovered his responsibility returned at the same time

With regard to allowing nonexpert witnesses to express opinions as to the mental soundness of a person at a certain time the rule in Kentucky is to allow a nonexpert witness to give his opinion as to the mental condition of another only after he has testified to facts showing a familiarity on his part with the life, habits and conduct of the one whose mental condition is under consideration, and, even then, his opinion this court has held, is not so important as the evidence which he gives showing the idiosyncrasies or normalcy of the mind of the one under inquiry In other words the opinion of a nonexpert witness as to the mental status of another cannot be received in evidence because it has no probative value unless it is supported by a statement of facts from which the opinion can be and is reasonably deduced, and the opinion can be of no greater value as evidence than the facts on which it is based

Fat Requirement of Children—Holt and Fales assert that a certain amount of fat should be supplied to provide fat soluble vitamin This amount is not yet known Fat probably has an important influence on mineral metabolism especially on calcium metabolism Fat is probably necessary for proper digestion and utilization of protein and on this account it seems desirable to supply as much fat as protein in the diet Fat helps to maintain normal physical, bacteriologic and chemical conditions in the intestine It also exerts a protective action against the irritating effects of the products of carbohydrate fermentation A great reduction of fat in the diet increases the susceptibility to infection, especially to tuberculosis The authors urge that the grounds for the current impression regarding the harmful effects of fat on children should be investigated carefully There is little evidence that a liberal amount of fat in the diet is harmful to children with normal digestion and much evidence that fat is an important and necessary component of the diet during the entire growth period In general, it seems rational to supply in the diet of the child as much as 4 gm fat per kilogram daily at one year, decreasing the amount to about 3 gm per kilogram at 6 years and maintaining this value throughout the remainder of the growth period

Frequency of Tuberculosis in Children—The method employed by Hamburger is this All children to be examined are first subjected to a cutaneous or percutaneous test with concentrated tuberculin Those who do not react, from twenty-four to forty-eight hours later receive a subcutaneous injection of 0 01 mg tuberculin Those who do not react after the second injection are given a third injection after a further twenty-four hours If the test is negative, another injection is given after the lapse of another twenty-four hours, or at most forty-eight hours the dosage being raised to 1 mg If the place of injection does not show any reaction, such as definite redness and infiltration the child may be regarded as free from tuberculosis with nearly absolute certainty In doubtful cases, an injection of 10 mg is given

Idiopathic Aplastic Anemia—Herrman reports a case in a child, 4 years old, in which marked improvement was obtained from transfusion of 380 c c blood from her father

Alkali Reserve in Spasmophilia—In three cases of spasmophilia in infants studied by Calvin and Borovsky no evidence of 'alkalosis" was found In fact there was a tendency for the alkali reserve to be lowered during the spasmophilic stage and gradually to be increased as the cases recovered

Immunization Against Diphtheria—During a four years' period all nurses with positive Schick reactions were given injections of toxin-antitoxin by Cooke and as a result more than 80 per cent were immunized In a small number the Schick reaction remained positive after two series of toxin-antitoxin injections As a result of the immunization, there was a decrease in the incidence of clinical diphtheria among these nurses of at least 90 per cent as compared to a previous three years' period

Aspiration of Stearate of Zinc by Infants—Stearate of zinc has largely replaced talcum as a dusting powder in the nursery With its ever widening use there has developed a striking increase in the number of disastrous results of infants from its accidental aspiration Heiman and Aschner present a clinical study of twelve cases and the results of experiments with zinc stearate insufflation in animals The onset of trouble is sudden and stormy, with rapid respirations and cyanosis Complete asphyxia may occur In eight cases the initial partial asphyxia was followed by a gradual recovery without definite involvement of the lungs The rapid respirations and cyanosis which followed immediately on the inhalation of the powder subsided during the course of three days The temperature was only slightly elevated The stearate of zinc container as now prepared for the nursery is a distinct menace to the health of infants The authors ask the medical profession to eliminate this dangerous type of container from the nursery

Healing After Fredet-Rammstedt Operation—The stomach of twenty-five infants who came to necropsy with hypertrophic pyloric stenosis were examined by Wollstein Two children died before operation, and the rest succumbed from twenty-four hours to two years after the Fredet-Rammstedt operation had been performed The lesion in hypertrophic pyloric stenosis is a hyperplasia of the unstriped muscle cells of the circular coat, while the connective tissue is not increased After the Fredet-Rammstedt operation healing is brought about by the cells of the serosa and submucosa, but the unstriped muscle cells take no part in the process The wound in the pylorus is healed within nine days The pylorus has become relaxed within two weeks The stomach has returned to its normal size within a month and the gap between the cut ends of the muscle coats has practically disappeared in six weeks In two years only a thin line of connective tissue fibers separates these two muscle ends, and the stomach is quite normal In contrast to the operation of gastro enterostomy which leaves the pylorus unchanged, the Fredet-Rammstedt operation cures the pyloric lesion

Eruptive Disease in Children—Twenty-one cases of what Zahorsky has termed 'roseola infantum," are analyzed by Park and Michael The outstanding features are the abrupt onset the high fever of from three to five days' duration without apparent cause, and the appearance of a morbilliform rash coincident with a critical fall of temperature to normal Additional points of distinction are the apparent noncontagiousness, and the predilection of the disease for infancy Moderate leukopenia and lymphocytosis appear to be the only significant laboratory findings This condition is distinctive and appears to be a clinical entity The etiology is unknown

Value of Intracutaneous Tuberculin Test—In order to compare the results of intracutaneous tests with those of the Pirquet cutaneous test, Happ and Casparis did Pirquet tests in most instances at the same time as the intracutaneous tests In miliary tuberculosis and tuberculous meningitis in infants and children the Pirquet cutaneous test was positive in just over 50 per cent of the cases The intracutaneous test is more sensitive and as opposed to the Pirquet test it not only affords a method of accurately measuring the amount of tuberculin given but enables one to increase the amount at will The authors assert that if a high enough concentration of tuberculin is given intracutaneously, a positive reaction will be obtained in practically all cases of tuberculosis

Bacteriolysant Therapy of Dysentery—As far as can be judged from twelve cases of bacillary dysentery in children,

in which bacteriolytic filtrates in amounts of from 5 to 1,381 c c were administered by Davison, bacteriolysant therapy did not influence the mortality or the course of the disease

*Treatment of Diphtheria Carriers by Means of Roentgen Ray P M Hickey Detroit —p 319

Carcinoma of Prostate—Bumpus asserts that the average duration of cancer of the prostate, if untreated, is approximately three years Roentgenograms show that metastasis to the bone occurs in about one third of the cases of cancer of the prostate Metastasis from atypical carcinoma of the prostate, in which the cells, because of their tendency to early metastasis, produce only slight local enlargement, may frequently be mistaken for Paget's disease In order to treat successfully cancer of the prostate with radium it is necessary to use in the aggregate large doses (from 3,000 to 4,000 mg hours), exposing all parts of the gland to comparatively small doses The increased duration of life following radium treatment in cases of cancer of the prostate is in direct proportion to the amount of radium radiation applied No one method of application radiates all portions of the gland The malignant gland must be radiated by urethral and rectal exposures, and by needles inserted directly into the neoplasm in order to produce complete radiation of all portions Sacral anesthesia is a useful adjunct in the application of radium needles, making it possible to place the radium accurately and to change the position of the needles without pain, thus a more thorough radiation of the gland is accomplished

Treatment of Diphtheria Carriers by Roentgen Ray—Roentgen-ray treatments were given to diphtheria carriers by Hickey over the region of the tonsils, nose and mastoid areas, according to the type of the case In the throat cases, that is, those in which Klebs-Loeffler bacilli were found in pharyngeal secretions, the treatment was given on each side of the neck, the central rays being directed toward the tonsils In the nasal cases, the treatment was given directly over the nose, and in the ear cases over the mastoid area of the ear, which showed Klebs-Loeffler bacilli in the discharge Nineteen throat cases were treated, with a definite cure in fifteen of six nasal cases four were cured Nine cases of otitis media presenting Klebs-Loeffler bacilli were treated, with four cures A comparison shows that in untreated cases of diphtheria carriers, there was 34 per cent of spontaneous cures, cases treated with mercurochrome, 68 per cent of cures, pharyngeal cases treated by the roentgen ray, 80 per cent of cures

Typhus in Boston—On the basis of the estimated total of medical cases admitted to the Boston City Hospital during a ten-year period Shattuck says, the proportion of typhus diagnosed is slightly less than one case per ten thousand Failure to diagnose typhus seems to have occurred in the proportion of from one to two cases per ten thousand If this be true, the actual occurrence of fairly typical typhus cases during the past ten years was at the rate of from two to three cases per ten thousand admitted, but if any considerable number of atypical cases suggestive of typhus were in fact typhus, the figure should be higher The epidemiologic aspect of the question requires serious consideration because, should typhus begin to spread in Boston, the recognition of mild or atypical cases in their early stages would assume serious importance and the problems of differential diagnosis would be much the same as those encountered in the study of the hospital records

Immunity to Tuberculosis A K Krause, Baltimore —p. 233

Healing in Experimental Pulmonary Tuberculosis—To the general pathologist, healing of the lesions induced by the tubercle bacillus usually signifies fibrosis or calcification A relatively small group of tuberculosis experimentalists have for twenty years or more been familiar with a low virulent strain of tubercle bacillus capable of inducing a different type of healing, namely, a complete disappearance of visceral lesions from the body of the experimental animal The organism which these observers have used is known in the Saranac Laboratory as Rk. Isolated by Trudeau from a human case of meningitis in 1891 this organism has maintained a constant low degree of virulence The visceral lesions resulting from its inoculation tend to heal spontaneously but Gardner says none of them has worked out by histologic study the mechanism of the healing process The illustrations accompanying Gardner's article demonstrate the fact that the R 1 strain of tubercle bacillus is capable of producing lesions which progress to caseation, and that this caseation together with the accompanying proliferation of fixed tissue cells is then absorbed The healing process is one of resolution, of which no trace remains at the site of the former lesion

Chemotherapy of Silver and Arsenic Compounds in Experimental Tuberculosis—An investigation conducted by Smith on the chemotherapy of some arsenic and silver compounds in tuberculosis has shown that neo-arsphenamin and silver arsphenamin have a very slight inhibiting action on the growth of the tubercle bacillus in vitro Colloidal silver oxid has no effect whatever on its growth, while silver methylene blue has a very considerable inhibiting action on its growth None of these substances has any demonstrable effect on the pathogenicity of the tubercle bacillus when exposed to their action in vitro at body temperature for forty-eight hours None of these substances when administered to experimentally infected tuberculous guinea-pigs has any favorable influence on the course of the disease

Tuberculosis in Infancy—A case of double miliary infection by the human tubercle bacillus in a child, aged 11, is presented by Smith The outstanding pathologic features of the case were the unusual numbers of organisms which stain readily with methylene blue, the two separate and distinct crops of miliary lesions, and a peripheral gliosis in the cord and cerebrum The statistics on 200 consecutive necropsies from the Infants' Hospital are reported, showing an incidence of 20 per cent tuberculosis An analysis of these figures is made showing the distribution of the lesions and their significance.

Diagnosis of Tuberculosis in Children—Gibson and Carroll emphasize that the diagnosis of tuberculosis in children is

not a subject for dogmatism It is their belief, however, that active tuberculosis is invariably manifested by signs and evidences of bacterial intoxication As long as there is an active tuberculous focus in the body, some indication of constitutional toxemia will be discovered either by physical diagnosis—the best means—or by some test or reaction One of the most interesting procedures of this nature is the auto-urine test of Wildbolz Gibson and Carroll have used the test on 105 children and it has been of value in establishing a definite diagnosis of active tuberculosis in certain cases and of great assistance in ruling out nontuberculous conditions Fifty-six cases previously classified clinically reacted positively The test not only corroborated physical findings of activity in 98 per cent of cases but brought to light a definite diagnosis in six children whose conditions had not been finally decided on Negative results were obtained in forty-nine cases and with one exception these results were not at variance with the opinions reached after clinical examination The percentage of the diagnoses of nontuberculous conditions in these cases which were corroborated by the auto-urine tests was 97 9 Therefore, the auto-urine test deserves a definite place among the various methods employed in diagnosis of active tuberculous disease

Heliotherapy of Laryngeal Tuberculosis—Voorsanger emphasizes the value of heliotherapy in the treatment of laryngeal tuberculosis, particularly in the infiltrative and mild ulcerative stages where, if carried out conscientiously for a period of six months, complete arrest is possible One of the greatest benefits of heliotherapy is the alleviation of pain, especially in hopeless cases The solar therapeutic laryngoscope of composition metal materially increases the efficacy of the application of sunlight to the larynx, in that it permits protracted exposure without causing painful hyperemia

Effect of Carbon Dioxid on Tubercle Bacillus—Gauss study indicates that the concentration of carbon dioxid found to inhibit the growth of the tubercle bacillus occurs normally in the human body, and that this concentration probably does inhibit the growth of the tubercle bacillus, thus establishing this factor as significant in the resistance to tuberculosis

Study of Pernicious Anemia During a Remission—A case of pernicious anemia showing a remission during which the hemoglobin rose from 10 to 56 per cent in twenty-one days is reported by Grieg and Dennis With the rise in hemoglobin content were showers of erythroblasts and megalocytes as well as leukocytes and myelocytes Early disturbances of the sensory nerves and numbness of the limbs were complained of in 1914 The absence of free hydrochloric acid from the gastric secretions and a long history of recurring attacks of mild diarrhea, and the blood chemical findings of a slight nitrogen retention and an acidosis not associated with ketonuria seem to be in keeping with the chemical findings reported by others in this disease

Pharmacology of Acetone—Salant and Kleitman's experiments show that acetone possesses a double action causing depression as well as stimulation, but it is chiefly a depressant These results seem to contradict some of the statements in the literature concerning the action of acetone Salant and Kleitman never observed cardiac acceleration, nor could they corroborate the statement of Albertoni that after large doses respiration was regular As to the potency of acetone it is evident that its action is not very strong, but is nevertheless considerable It is particularly interesting to note that its effect was greatly augmented when a number of just active or subminimum doses were given Though the amounts of acetone present in the blood in acidosis are comparatively small, it should be borne in mind that the tissues and organs in the body may be exposed to its action for a considerable period There is therefore, no justification for the assumption that acetone is without effect in those conditions simply because its concentration in the blood is low

Mercury Causes Fall in Blood Pressure—Salant and Kleitman noted that the intravenous injection of the acetate, succinate and benzoate of mercury into cats, dogs and rabbits produced a sudden fall in blood pressure which was very marked and persistent Depression and later paralysis of respiration also occurred Cardiac inhibition was produced by the intravenous injection of the salts of mercury in cats, but not in dogs or in rabbits Decreased irritability of the vagus was observed in cats after the intravenous injection of the organic salts of mercury That the fall in blood pressure after mercury was of cardiac origin was shown by observations on changes in the volume of the kidney Perfusion of the turtle heart with the different salts of mercury produced cardiac depression irregularity and delirium cordis Concentrations of one part of mercury to one million parts of Ringer's solution and even one to ten million, were effective The frog's heart was more resistant to mercury than the turtle's heart No delirium cordis was observed The action of mercury is cumulative

Aeration of Posterior Accessory Sinuses in Acute Optic Neuritis L E White Boston—p 382

Liver Tunnel and Cardiospasm—Roentgenograms of the lower end of the esophagus often show it ending in a nipple-like point Between this and the fundus of the stomach there is a gap This varies in length but may measure 1 inch or even 1½ inches Mosher asserts that this gap is the closed liver tunnel in which the subdiaphragmatic part of the esophagus runs The lower end of the esophagus has liver on the right in front and in many cases a thin tongue of liver hooks round its left edge like a sickle In reviewing ten cases of cardiospasm Mosher found a stricture in all They are called cardiospasm because the obstruction occurred at the lower end of the esophagus, the esophagus ended in the characteristic nipple-like point, and swallowing of cold fluids increased the difficulty whereas swallowing of warm drinks made the passage of food through the esophagus easier The stricture found in these cases varied from a slight crescentic fold in the right quadrant of the esophagoscope in the region of the hiatus to a full annular stricture with a central open-

ing In the cases which showed the crescentic fold steady pressure with the end of the esophagoscope usually resulted in the tube slipping by into the normal esophagus below and through this into the stomach The withdrawal of the tube disclosed a vertical slit in the mucous membrane of the esophagus Three of the cases had a full stricture with a central opening This stricture was at the hiatus or rather at the upper edge of the liver On divulsing the stricture with the mechanical dilator a crescentic mounding was seen in the right field below it Steady pressure caused the tube to pass this and enter the subdiaphragmatic esophagus and then continue on into the stomach This mound, Mosher believes to be the upper edge of the liver In one case there was a narrowing of the whole length of the liver tunnel The cause of the annular stricture at the upper edge of the liver tunnel or of the narrowing of the whole tunnel will be found Mosher believes, in previous infection of the lesser omentum which may result in temporary or permanent narrowing of the liver tunnel

Puerperium from Standpoint of Neuropsychiatrist C. E Riggs St Paul —p 375

Causes of Failure After Appendectomy—Believing that a considerable amount of trouble complained of after appendectomy may be due to adhesions, Rowan regards as valuable the suggestion of Gibson to use 5 per cent picric acid in 95 per cent alcohol Its antiseptic action is as strong as tincture of iodin and its penetrating power as great, it is less irritating to skin and peritoneum, and peritoneal adhesions are not nearly so likely to occur following its use as a skin antiseptic After a careful study of his cases Rowan feels that the results of operation for chronic appendicitis are not satisfactory and that there is considerable room for improvement He suggests that these patients should have more careful examination and often more prolonged observation, especially if the condition is not in every way typical No patient should be regarded as having typical chronic appendicitis unless a history of a former characteristic acute attack is obtainable Extra care and consideration should be used before advising operation in neurotics especially those with colitis or visceroptosis More exploratory incisions should be used in preference to the muscle-splitting incision, and always in atypical cases, and the exploration should not end with the discovery and removal of a diseased appendix

Primary Carcinoma of Lung—When a patient has dyspnea, deep dull chest pain with hemoptysis and possibly some abnormal chest findings, Rizer and Habein state malignancy of the lung should be considered They report four cases in which the admitting diagnoses were tuberculosis, weakness of left arm and left leg, asthma, aneurysm or bronchiectasis and pleurisy with effusion, respectively The final diagnosis in these cases, in the order named, was primary carcinoma of the left lung, primary carcinoma of the lung with brain metastases, carcinoma of the right lung, with abscess and primary carcinoma of the right lung In each case the clinical diagnosis was confirmed at the necropsy and extensive metastases were found

Quinidin in Auricular Fibrillation—In view of the possibility of the occurrence of occasional embolic phenomena and of serious disturbances in the cardiac rhythm Levy urges that until the criteria for choosing favorable cases are more clearly defined patients with auricular fibrillation receive quinidin in bed, under careful supervision and preferably in a hospital where the behavior of the heart can be studied with the aid of graphic records Carefully administered, this drug is a therapeutic agent of great value, indiscriminately given it may, on occasion, be expected to cause disastrous effects

*Organisms for Two Sporadic Cases of Cerebrospinal Meningitis C Monserrat —p 15

Organism Isolated from Cerebrospinal Meningitis—The organisms isolated in the two cases of meningitis reported by Monserrat resembled morphologically and in staining characters the true meningococcus, differing however in the rapid profuse growth obtained in all ordinary mediums from the beginning, their ability to grow at room temperature, and their inability to ferment any sugar medium The formation of uniform emulsion in physiologic solution of sodium chlorid is a constant character of these two strains resembling in this respect the normal meningococcus, though there is a certain tendency to agglutinate spontaneously when observed microscopically in 0 85 per cent salt solution The absence of pigment in the growth on ordinary and special mediums distinguishes these organisms from the chromogenic D flavus group At the same time they differ from the D flavus-like organism isolated in one case previously reported by Monserrat, in that they are not agglutinated by a serum specific for that organism The facts that the present organisms were not affected equally by different antimeningococcic serums, and that with all of these serums except one rather low dilutions were necessary in order to produce reaction lead Monserrat to the conclusion that probably his strains belong to the intermediate group often found in sporadic cases and generally spoken of as aberrant strains or parameningococci These are more or less related serologically to the true meningococcus varieties, differing chiefly in their sugar reactions

Granuloma Inguinale—Randall and his associates are convinced that granuloma inguinale, long considered a tropical disease, is endemic in the temperate zone of the United States Its diagnosis is dependent on (1) the characteristic local lesion, (2) the marked predominance in the negro race, (3) and the finding of the specific organism originally described by Donovan These organisms the authors have demonstrated in smears from granuloma lesions in twelve patients in a series of sixteen In the other four instances laboratory examinations were not made An encapsulated bacillus, which when stained from cultures, resembles this organism, has been isolated from three of the twelve patients studied culturally This bacillus is a member of the *Bacillus mucosus-capsulatus* group Abscesses with spontaneous rupture and ulcer formation have been produced in rabbits by subcutaneous inoculation These heal spontaneously in from three to seven weeks and grossly cannot be regarded as granulomas although the walls of these abscesses on histologic examination present granulation tissue not to be differentiated from that of the granuloma lesions Friedländer's bacillus forms similar lesions A few experiments attempting to establish symbiotic relationships between the encapsulated bacilli from granuloma lesions and staphylococci, colon bacilli, and diphtheroids in experimental lesions have failed Treatment with tartar emetic intravenously acts as a specific, and rapid healing may be expected with the prompt disappearance of the specific organism No contraindication to the intravenous use of this drug up to doses as high as 0 1 gm have been met

Icterus Index of Blood Serum—Muehlingradt recently described a method for determining bile pigments in the blood Briefly, it consists of comparing blood plasma with a standard solution of potassium bichromate and diluting the plasma with physiologic solution of sodium chlorid until its color approaches that of the standard The potassium bichromate solution (1 10,000) is approximately equivalent to the color of a nonicteric plasma Maue has modified this method, using serum instead of plasma The technic is as follows A solution of potassium bichromate 1 10,000 is used as a standard From 5 to 10 c c of blood are obtained, and the serum allowed to separate The serum is compared in a colorimeter (Duboscq) with the standard bichromate solution The standard may be set at 10, 15 or 20 mm The icterus index is obtained by dividing the reading of the standard by the reading of the unknown When the color of the serum is too dark and cannot be compared with the standard solution, the serum is diluted with physiologic solution of sodium chlorid until its color approaches that of the standard In 156 cases giving no clinical evidence of jaundice, the lowest value obtained was 1 6 (fracture of skull), while the highest was 12 (pernicious anemia), the average being 3 6 An icterus index varying between 2 5 and 6 may be considered as normal

Pathognomonic Sign of Intra-Uterine Death—From a study of fetal skulls with the roentgen ray in thirty-one cases of pregnancy Spalding has found that with live babies the fetal skulls appear normal, except for the effect of labor which produces an overlapping of the skull bones In three cases of intra-uterine death, the roentgen ray showed the marked overlapping of the skull bones with distinct signs of shrinkage of the skull contents From these facts Spalding believes it is justifiable to state that shrinkage of the skull contents with overlapping of the skull bones can be demonstrated with the roentgen ray, which gives a pathognomonic sign of intra-uterine death

Experimental Pyloroplasty—The Rammstedt operation, or so-called "partial pyloroplasty," according to Miller and his associates is, when conditions will permit, the most effective way of enlarging the pylorus It has the advantage of being the simplest operation yet devised for this purpose and requires very little time under anesthesia A plastic flap operation is unsatisfactory on account of requiring such extensive incisions into the lumen of the canal It is also unsatisfactory on account of its tendency to retract and restore the divided pyloric sphincter

Experimental Reconstruction of Esophagus—A simple experimental method has been devised by Neuhof and Ziegler in which a granulation tube is employed for the reconstruction of the esophagus after its resection A two-stage procedure is requirement The desired portion of the esophagus being thoroughly isolated, gauze packings are placed beneath it, the ends coming out of the wound The latter is left wide open At the second stage one week later, the isolated portion of the esophagus is elevated by the traction on the packings and is divided obliquely above and below The packings and the segment of esophagus are then removed A bed of granulation tissue is found to have formed beneath the packings A soft rubber tube of the diameter of the esophagus is securely sutured to the upper and lower ends of the organ by stitches passed transversely When the tube becomes loose it is removed if it has not already been discharged from the wound A granulation tube forms with epithelial overgrowth from the esophageal ends beginning in one week and becoming extensive at the end of three weeks The longest period of observation was seven months after operation In this case the new-formed tube was well developed and completely lined by esophageal epithelium A partial stenosis appeared soon after operation but was not progressive The method is advocated as applicable for reconstruction of the esophagus after resection for cancer

Calculi in Brain—The case described by Miller differs markedly from those found in the literature in that the roentgenologic examination revealed shadows which had the appearance of stones or calculi within the brain substance and these were successfully removed at operation

Secondary Perineal Repair—The puborectalis muscles are the point of attack in Cherry's operation because, he asserts, the structures injured at the completion of the second stage of labor producing subsequent relaxed perineum and rectocele, are the pubococcygeus muscle bundles of the levatores ani, their fascial sheath (retrovesical and anal fascia), and the triangular ligament In order properly to correct the disturbed anatomic relationship of the puborectalis to the rectum it is necessary to approximate them with their fascial sheaths in the midline anterior to the rectum To restore the vulva and vaginal support which depends on the triangular ligaments it is necessary to shorten this structure and place it in close contact with the levator muscle and sheath The operative technic described by Cherry fulfils these conditions in that it reestablishes the perineal structures in their anatomic relation

Quinin and Castor Oil to Induce Labor—Quinin and castor oil in inducing labor, Williamson states, are successful in approximately 50 per cent of cases Labor should be carefully watched, for occasionally there may be tetanic contractions At the first sign of fetal or maternal distress, the operator should be ready to interfere If there are signs of cinchonism, the quinin is to be stopped at once The most favorable conditions for this type of induction are When the estimated date is due or past, when the head is fixed or beginning to fix in the pelvis and when the uterus is irritable The mechanism is due to irritation caused by the castor oil of the sympathetic centers with increased peristalsis and a reinforcement of the rhythm and muscle tonus by the quinin acting directly on the uterine muscle bundles

Treatment of Proemial Breast—No surgeon of experience can be satisfied with the results obtained by the present surgical treatment of cancer when it arises primarily in the breast Cheatle directs attention to the existence of a potentially dangerous state of the breast, and indicates the advisability of removal of a breast in this state rather than wait for the evidence of disease for which surgical measures have been proved to be so unsatisfactory The condition of the breast which is a prelude to those particular pathologic changes Cheatle terms the "proemial breast' The proemial breast is worthy of due recognition for two reasons (1) It is in a state that makes it a prelude to further pathologic changes of a highly important character—mainly simple papilloma malignant papilloma, and other forms of cancer (2) Its clinical recognition and adequate treatment occasionally enables the surgeon to recognize (microscopically) the presence of one or more of these changes, before any clinical sign of their existence is obtainable by any other means—that is to say when the proemial breast has merged into those profoundly important stages to which it has acted as a prelude When once established the condition of the proemial breast is permanent The symptoms are swollen painful and tender nodules not of the same size in corresponding parts of the same gland There may be an intermittent or continuous discharge of serum from the nipple A thin layer of coagulated serum may be seen on the surface of the nipple The discharge is always small in amount In the later stages of this complaint the pain disappears and cysts are present in varying number The proemial breast bears exactly the same relationship to cancer and papillomas of the breast as the proemial appendix does to general peritonitis Cheatle's treatment of the proemial breast, in whatever stage it exists, is to remove it

Unusual Cause of Death in Laryngeal Cancer—Linell relates the case of a woman, aged 43, suffering from an inoperable carcinoma of the larynx which had required tracheotomy to relieve urgent symptoms She was comfortable until early in morning of the twenty-fifth day, when she awoke with severe pain over the precordium The pulse became almost impalpable and the heart sounds were very weak, but there was no dilatation of the organ and no bruits could be heard There were moist sounds at the base of the left lung These were the only antemortem findings of note except for slight sepsis round the tracheotomy tube The patient died the next day The postmortem examination disclosed a left sided pleurisy, abscess of left lung ruptured into the pleural cavity, nodular secondary growths on the pericardium and the left pleura, deposits in the bronchial glands, and in the right auricle, a papillomatous mass the size of a pea was found projecting into the cavity from the smooth endothelial wall Histologic examination of this growth showed the typical structure of squamous cell carcinoma From the facts that it was infiltrating the subendothelial heart muscle and separating the muscle fibers it would appear that the embolus had arrived via the blood or lymphatic system and that it was not an implant on the auricular endothelium from embolism down the superior vena cava

Venous Thrombosis Sign of Malignant Disease—Moorhead states that the diagnostic value of intravenous thrombosis as a sign of visceral malignant disease seems hardly to have attracted the attention that it deserves, or rather it appears that while universally admitted to be a not unusual phenomenon in states of advanced cancerous cachexia, it is hardly realized that it may occur as a comparatively early symptom or even as the earliest symptom of a latent carcinoma Four cases are cited by Moorhead which bear out the value of this observation that there is a group of cases of latent cancer of the stomach with peripheral venous thrombosis as the earliest, and indeed only, prominent symptom throughout

Differential Diagnosis Between Cholelithiasis and Duodenal Ulcer W J McKenna—p 1096

Lymph Glands and Tuberculosis—Observations made by Herring and Macnaughton support the validity of the doctrine spoken of as Cohnheim's law which states that the tubercle bacillus reveals the site of its entry into the body by setting up characteristic changes in the lymph glands which receive lymphatics from the area in which it enters There is no evidence of a new formation of lymph glands in tuberculous conditions Microscopic glands exist and become enlarged, but much of the tissue associated with tuberculous glands is merely tuberculous tissue which bears a superficial resemblance to lymph glands in whatever situation in the body it occurs

Treatment of Carditis—The treatment of carditis, Hutchison says offers few opportunities for active intervention—rest and patience are chiefly required, and too active therapeutics may do more harm than good

Agglutinins in Normal Serum for Paratyphoid Group—Rosher and Fielden have found that among the general population a considerable proportion of individuals yield serum agglutinating *B paratyphosus* C, *B aertrycke* (Mutton), and *B enteritidis* (Gaertner) Some evidence is brought to show that the agglutination of *B aertrycke* and *B paratyphosus* C is largely due to secondary agglutination from the paratyphosus B element of the triple vaccine, whereas *B enteritidis* (Gaertner) seems to be coagglutinated both by the typhoid and paratyphoid B elements If a diagnosis is to be made on a single agglutination reaction, the titer must be very considerably higher than 1 640 for these organisms A titer of over 1 1,000 is suggestive of infection with the organisms concerned, and a titer of over 1 2,000 is strongly suggestive of the same conclusion, but in all cases it will be necessary, if an accurate diagnosis is to be arrived at, to perform repeated tests and to demonstrate fluctuation in the agglutinin content of the patient's serum which is now generally recognized as characteristic of infection with organisms of this group and which the studies of Dreyer and his associates have made it possible to follow accurately hitherto unobtainable

Colloidal Benzoin Reaction of Normal Cerebrospinal Fluid—From Dible's experiments it would appear that the negative reaction occurs with normal cerebrospinal fluid The positive reaction indicates an alteration in the cerebrospinal fluid which is very probably syphilitic in nature An ambiguous reaction indicates a pathologic condition in the cerebrospinal fluid, but does not indicate its exact nature

Significance of Discharge from Nipple in Breast Lesions—Among 251 cases of lesions of the breast reviewed by Lewis there were only 26 patients, all of them women who gave a history of discharge from the nipple In these 26 cases the lesions were as follows spheroidal cell carcinoma, 9, chronic mastitis (cystic and noncystic), 6, duct carcinoma, 4, duct papilloma, 4, Paget's disease of the nipple, 1, abscess, 1, seborrheic dermatitis of the nipple 1 In the case of spheroidal cell carcinomas, the total number of patients treated in ten years was 129, giving a percentage of about 7 with discharge The percentage in chronic mastitis was 13 3, in duct carcinoma 36 3, and in duct papilloma 100 Of forty-four cases a history of discharge was given in 6—e g, duct carcinoma, 1 (out of 4 specimens of this disease), spheroidal cell carcinoma, 3 (out of 18), chronic mastitis with multiple cysts, 1, malignant disease of the nipple, 1 In the single case of duct papilloma in the collection, in which the duct has dilated to the size of a small orange, the presence or absence of discharge is not mentioned in the history In each case in which discharge was present the lesion lay immediately beneath the nipple In all the malignant cases except one, the patient had noticed the presence of a swelling in the breast for some time previous to the appearance of the discharge Therefore, discharge from the nipple is not in itself a definite expression of malignancy and should not be treated as such unless the suspicion is strengthened by the rest of the history and clinical picture

Large Antrochoanal Polyp—The polyp in Dawson's case weighed 9 5 drams and filled the nasopharynx, bulging the soft palate forward Respiration or deglutition was impeded Beyond the peculiar muffled speech, and the occurrence of fits of suffocation should he happen to turn on his back during sleep, there were no symptoms

*Importance of Uterosacral Ligaments in Uterine Prolapse. C A Thelander—p 511
*Tumors of Brain Pathology and Treatment H R Dew—p 515
Schaefer Method of Artificial Respiration T S Dixson—p 521
Acute Poliomyelitis M O Sullivan and J G Sleeman—p 523

Restoration of Uterosacral Ligaments for Prolapse—Thelander believes that restoration of the uterosacral ligaments approximates closer to a physiologic condition than any other operation for prolapse After restoration of these ligaments the stress of normal labor may be withstood without recurrence of prolapse Plication of the ligament gives better results than parietal reattachment The operation can easily be supplemented by one of the round ligament suspensions if thought necessary Where uterosacral support is adequate no other operation is necessary

Tumors of Brain—Among the eighty-five cases analyzed by Dew were 30 gliomas, 6 endotheliomas, 1 sarcoma, 4 secondary tumors 2 simple cysts, 2 papillary cancers, 4 gummas, 1 tuberculoma, 1 adenocarcinoma and 5 hydatids Headache was the commonest symptoms, mental changes were noted in fifteen patients Aphasia was noted in five Convulsions were noted in twelve patients and as initial symptoms in eight Ataxia was noted in connection with three frontal tumors Optic neuritis was present in forty-six Nystagmus was present in sixteen patients suffering from cerebellar tumor In reviewing the facts as put forward the diagnosis and treatment are disappointing when compared Too often surgical intervention was delayed too long because of delay in diagnosis With the fuller adoption of the newer aids to diagnosis there is no doubt that few of the subtentorial tumors will escape detection and more of the others will be correctly localized

Erysipelas and Streptococcal Septicemia A Erian—p 373

Diathermy in Malignant Disease of Mouth—In faucial growths, the ease with which diathermy can be employed the lack of hemorrhage, preliminary tracheotomy splitting of the cheek or other operation Harrison says makes it very much more satisfactory and safer than a cutting operation Unfortunately, growths in this situation are often only passed over to the surgeon who uses diathermy when they are inoperable by the knife but in spite of this many patients have remained free from recurrence two, three or more years after the operation, and many others have had their lives prolonged, and their symptoms greatly relieved for shorter periods Harrison is certain that if earlier cases in this situation were operated on by this method the results would be more satisfactory than in cutting operations

Diathermy in Malignant Disease—In order to treat a case of malignant disease satisfactorily by diathermy, Steward says two conditions are essential apart from the provision of an efficient apparatus These two essentials are good illumination and complete exposure If, for instance the growth is situated within the mouth a good headlight is necessary, and by means of gage retractors, sutures through the tongue and if necessary splitting the cheek the whole of the affected area must be brought into plain view for no good can be expected to result from working in the dark Treatment by diathermy is capable of wide application, it is, for instance, available for many cases of malignant disease involving the tongue, the floor of the mouth the fauces the palate, certain parts of the pharynx the vulva, and vagina Of growths of the skin although the majority are better excised with the knife rodent ulcers are particularly suitable for treatment by diathermy

Painful Heel—By far the most prevalent type of painful heel, Stiell states is the condition known as "bruised heel" The second most frequent cause of pain in the heel is a true Achillo bursitis, which is an inflammatory condition in the bursa between the Achilles tendon and the posterior surface for the tuberosity of the os calcis This condition is usually produced either by continued trauma from an ill-fitting boot or shoe, or is a local manifestation of generalized rheumatic or gouty bursitis Another prevalent cause of acute pain of sudden onset around the heel is a true tenosynovitis of the Achilles tendon This condition is known by the name of achillitis, and is practically always traumatic in origin It is sometimes known as *sprinter's heel, but is equally prevalent* among sportsmen in general Another cause is tuberculous osteomyelitis, although it is only in the later stages of this condition that pain becomes a prominent symptom A gonococcal inflammation of the plantar fascia is an infrequent cause of pain in the anterior portion of the ball of the heel Calcanean spur is a comparatively rare cause of heel pain

How to Use Tuberculin—Robertson uses a mixed bovine and human tuberculin, beginning with an initial dose of 1/50 000 mg, future treatment being based on the reaction

*Vital Capacity in Pulmonary Tuberculosis C Cameron—p 385
*Relationship of Tuberculosis and Injury N Tattersall—p 400
Severe Emphysema Complicating an Artificial Pneumothorax A Aronson—p 403

Vital Capacity in Pulmonary Tuberculosis—The estimation of the vital capacity by a suitable spirometer, Cameron states, is a simple clinical test, which even in pulmonary tuberculosis *is attended by the minimum of ill effects* No ill effects were observed in the course of 6,000 observations The vital capacity is always reduced in pulmonary tuberculosis, a fact of considerable significance in the diagnosis of doubtful cases It should however, be borne in mind that other lung diseases than tuberculosis may effect a reduction The vital capacity, with certain reservations, is reduced in proportion to the grade of the disease There are grounds for considering that two elements are concerned in his reduction (*a*) the element of toxemia, (*b*) the element of pathologic structual tissue change In the early case the probability is that the toxic element is the main factor in causing reduction In the more advanced case both elements play their parts The significance of the reduction can only be interpreted in association with the results of careful clinical examination The vital capacity in pulmonary tuberculosis varies according to the state of the patient, increasing when improvement takes place and decreasing during periods of physical retrogression An increase of vital capacity is, in this respect, per se, an absolutely reliable guide to the progress of the patient A stationary or slightly decreasing, vital capacity, usually *denotes an unsatisfactory pulmonary condition, but in such* cases the vital capacity must be considered in association with the clinical findings, and other possible causes of diminution eliminated Advancing disease is always associated with diminishing vital capacity, but diminishing vital capacity need not necessarily indicate advancing disease The vital capacity is of restricted value in estimating the work capacity of the victims of pulmonary tuberculosis Excessive vital capacity diminution is not compatible with work capacity but the more moderate grades of diminution bear no definite relation to work capacity The upsetting factors here are the varying parts played by the anatomic and toxic elements in the reduction of vital capacity The fairly advanced but temporarily quiescent type of case, may have a vital capacity considerably reduced by causes which are largely anatomic, and yet have within limits a good work capacity The moderately early case in which anatomic change is slight but disease is active and toxic manifestations controllable only by comparative rest, may have a much higher relative vital capacity, and yet be quite unfit for any grade of work

Relationship of Tuberculosis and Injury—*To* correlate injury and tuberculosis, Tattersall says, the symptoms must appear promptly (within a few days or weeks) after the injury The lighting up of an existing focus is infinitely more frequent than subsequent implantation in damaged but healthy lung Foci in the mediastinal glands play a more important part in these cases than has generally been supposed

*Renal Diabetes M Labbe—p 273
*Auto Observation of Epidemic Encephalitis P Cantaloube—p 285
*Splenopneumonia A Pelle—p 300
Spontaneous Aneurysm Involving Aorta and Vena Cava. J Chalier and F Barret—p 306
*Curable Tuberculosis in Infants R Debre and P Joannon—p 320
*Mercuric Chlorid Poisoning G Guillain and C Gardin—p 338

Renal Diabetes—Labbe reports a case of renal diabetes under observation from the age of 6 to 18 The general condition has always been good notwithstanding this permament excessive permeability of the kidneys for glucose The elimination of sugar at times amounted to 44 gm It was *scarcely affected by the diet, but there was a slight orthostatic* tendency and there was also orthostatic albuminuria Intravenous injection of calcium chlorid seems to reduce the permeability of the kidneys for glucose He treated this patient by this means, and when last seen she was *eliminat-*

mg only 0.25 gm of glucose and 0.04 gm of albumin in the twenty-four hours

Auto-Observation of Epidemic Encephalitis—Cantaloube presented intense ovaluria and crossed trigeminus-facialis paralysis, besides the usual kaleidoscopic clinical picture of grave epidemic neuraxitis. He was not able to resume his practice until October, 1921, just before the close of the second year. He appears to have recovered completely, and now weighs 2 kg. more than he ever weighed before. He was confined to bed for over three months in the whole course of the disease. He declares that no medication displayed any efficacy. No attempt was made to induce a fixation abscess, and he did not try hexamethylenamin, but almost the entire therapeutic resources otherwise were tried and abandoned, from ergot to sulphur, with organotherapy and large doses of tincture of iodin. No action was apparent from any of them except possibly from calcium chlorid, lead acetate and phosphoric acid. Tobacco was the only substance that displayed any decisive action, and this was in the line of aggravation of the symptoms. The disease is described from the standpoint of the medical victim. The peculiar instability of the arterial tonus is emphasized, and the visual, auditory and meningeal reactions and intense pains in joints.

Pneumonia with Splenization of the Lung—In Pelle's 7 cases of splenopneumonia, the condition had been mistaken for a subphrenic abscess in 2 cases, and on this basis a useless operation had been applied. In 3 cases the patients were being treated for supposed active pulmonary tuberculosis. In the 2 other cases pleurisy had been diagnosed. The trend toward recovery in two or three months, with retrogression of the roentgen-ray findings and negative bacteriologic examinations, confirms the diagnosis of the comparatively harmless splenopneumonia.

The Florid Form of Tuberculosis in Infants—In the eight cases described the children had the aspect of health, and they have developed normally. The only signs of their infection are a positive tuberculin skin reaction and one or more enlarged glands in the chest. The source of infection was not very virulent and the contact had been brief. This florid form represented 15 per cent. of tuberculous infants examined. If superinfection can be warded off, these children have every prospect of keeping their tuberculous focus latent or healing it completely.

Mercuric Chlorid Poisoning—Guillain and Gardin illustrate with a clinical case the vicious circle that is set up by mercuric chlorid. The acute nephritis which it induces causes retention of nitrogen, and this entails an acute toxic action from which the heart suffers, so that the danger really is from the heart. Treatment should aim to sustain the heart as the vital indication. By thus reenforcing the heart we can tide the patient along until diuresis sets in—which is usually about the fifth day. This clears out the waste products, and the primordial danger, the nitrogen poisoning, is thus averted. In their case mercury was refound in the spinal fluid, but the fluid was scanty, suggesting an action on the choroid plexus like that on the kidneys responsible for the anuria. The production of bile did not seem to suffer. Some cases with a favorable outcome are cited, in three weeks the patients were out of danger.

*Prophylaxis of Diphtheria. J. Renault and P. P. Levy.—p. 547

Apparatus for Screw Treatment of Fracture of Neck of Femur—Four illustrations show the details of Contremoulins' device with which it is possible to drive a screw or peg axially through the neck into the exact center of the head of the femur.

Prophylaxis of Diphtheria—Renault and Levy think they have improved on the Park and Zingher method by their practice of mixing the toxin and antitoxin only as the mixture is to be injected. They also use a mixture which is neutralized to excess. This strong hyperneutralization protects against all possible dangers. Out of the total thirty-two children thus treated the results were recorded in twenty-eight over several months. There seems to be a passive immunization during the first two weeks. Then this subsides and active immunization becomes installed, between the second and fourth months, in about 50 per cent. By the fourth to the sixth month nearly all have acquired it.

Bulletin Medical, Paris

May 13, 1922, 36, No. 20

*Meningococcus Septicemia. J. Reilly.—p. 379
*Recurring Mental Disturbance in Degenerates. R. Benon.—p. 383
*Glycosuria in Gout. C. Finck.—p. 389

Meningococcus Septicemia—Reilly's experience confirms that any of the types of meningococci are liable to induce septicemia. The micro-organisms may lurk in tissues adjoining the meninges and sally forth at times from these *gites parameningés* to invade the cerebrospinal fluid or the general blood stream. The paradoxic fact has been noted that meningococci from these parameningeal lurking places passing *into the blood stream, are refractory* to general serotherapy but yield to intraspinal treatment. Meningococci passing only secondarily to invade the meninges are more susceptible to general serotherapy. The combination of intraspinal and intravenous serotherapy represents great progress.

Recurring Mental Disturbance in Degenerates—Benon warns to be on the lookout for this *delire des degeneres* in subjects between 18 and 30 presenting sudden asthenia and tendency to melancholia. In a case described, the two attacks with depression in the young man were most certainly not neurasthenia, dementia praecox or a periodical psychosis. The attacks developed after emotional stress, the asthenia without known physical cause becoming pronounced in a few hours with illusions, hallucinations, headache, cold sweats and tendency to suicide.

Glycosuria in Gout—Finck has noticed a kind of balance between the excretion of uric acid and of sugar in gout. As one increases the other drops, but fully 20 per cent. of all his gouty patients developed glycosuria, and it progressed to actual diabetes in about 10 per cent. The retention of uric acid was most pronounced the days of the highest glycosuria and vice versa. The retention of uric acid was manifestly favored by hypo-alkalinity of the body fluids. Restriction of meat and treatment as for gout in general improved conditions as to both uric acid and sugar. He gives the details of eight cases long under observation, out of a total of thirty-three cases of glycosuria in the intervals between attacks of gout. It was a mild intermittent glycosuria, gradually becoming continuous, but without polydipsia or polyuria. Meat usually aggravated *the glycosuria*.

Bulletins de la Societe Medicale des Hôpitaux, Paris

*Distribution of Leukocytes in Scarlet Fever. T. Mironesco and A. Codreano.—p. 752

Pepsin Reduces the Blood Pressure—The experimental and clinical research described suggests that the resorption of pepsin during digestion may have something to do with the circulatory disturbances in dyspepsia by its action on the vagus. The blood pressure under its influence drops in cases of high tension and this effect lasts longer than in normal subjects. The subcutaneous injection of from 20 to 40 cg. of pepsin may therefore be advised. Loeper and Mougeot say, as a regular treatment of hypertension, especially paroxysmal hypertension. The drop averages 2 cm. mercury.

in the normal, and with high blood pressure may amount to 4 5 cm The effect was evident in five minutes, and the pressure did not begin to rise again for a whole hour There were no subjective disturbances, and the heart rhythm was not affected, while the effect on the blood pressure was as pronounced as with the best pressure reducers known, even the nitrites

Emphysema of the Lung—A descending rhinobronchitis entails chronic coughing, and the breathing through the nose is defective The consequence is a debility of the connective and elastic tissue of the lungs, the alveoli become abnormal, and thus conditions are ripe for the mechanical strain from the cough to start emphysema

Anaphylaxis from External Applications—Two cases are reported in which cade oil applied to the skin induced local and vascular reactions indicating pronounced anaphylaxis Desensitization was realized in the course of one month by local application of minute and progressive amounts of the same oil These cases warn to seek for anaphylaxis and the hemoclastic crisis in skin diseases, and try to desensitize through the epidermis In the following article, Gougerot and Blamoutier report an occupational anaphylaxis eczema from working on ebony wood The man was desensitized with an alcoholic extract of sawdust from the same wood The anaphylaxis in this case had been two years in developing, and the desensitization was realized in eleven days

Cardiovascular Thrombosis—The woman of 32 presented febrile asystolia and purpura, with severe hemoptysis, and necropsy revealed both auricles filled with clots, partly adherent

Distribution of Leukocytes in Scarlet Fever—Mironesco found in nine cases of scarlet fever and five of other diseases that in scarlet fever the proportion of leukocytes in the capillaries is much larger than in the veins He theorizes to explain this as a defensive reaction

Conical Resection of Uterine Cervix P Douay—p 377

Artificial Extraperitoneal Cesarean Section—*Magalhães* applies this term to abdominal cesarean section when the exposed uterus is covered with two overlapping sheets of dental rubber dam (1 x 0 5) which are held in place by a rubber band slipped over the uterus, as he shows in an illustration This rubber tissue fits over the uterus and is packed *into the abdomen* around, thus completely isolating the uterus from the abdominal cavity The overlapping edges of the two sheets on top of the uterus are drawn apart and the uterus is incised between them The evacuation of the uterus thus proceeds without the slightest danger of contamination of the peritoneum Confident in the outcome, he has applied this technic in 148 cases, and the total mortality of the mothers was 7 8 per cent although six of the eleven women who died had high fever and extensive ruptures of vagina and cervix from long and vain efforts to deliver by the normal route before they had been brought to the Maternity He does not know of any other obstetrician with such a record The postoperative course in his 148 cases was febrile in thirty-eight, but twenty-six had a temperature of over 39 C before the intervention, thirty-four, between 38 and 39 C, and thirty-eight had between normal and 38 C In thirteen cases of permanent contraction of Bandl's ring, all the women were saved but one severely injured by preceding obstetric procedures

Pathogenesis of Myomas—In 455 myomatous young women examined, 39 per cent, were of the type of Stiller's congenital muscular asthenia and 5 2 per cent of the type of hypertrophy of the muscular apparatus

Exophthalmic Goiter—Falconcini found the blood pressure high in all his twelve cases of exophthalmic goiter, but the proportions between the systolic and diastolic pressure seemed to indicate a diastolic hypotension, masked by the tachycardia The pulse was apparently normal except for its catacrotism and the instability evident in changes of position and under emotions In only four of his six cases of well defined exophthalmic goiter was the heart of the shape and size known as goiter heart, and in none of the cases of the incomplete type

Syphilis Contracted from a Bite—Martini relates that a sister of 16 tried to separate her two older brothers who were fighting, and in the melee she was bitten on the hand by one of the brothers, *who had also bitten the nose of his* brother The sixteenth and twentieth days after the affair

the girl and the brother developed syphilitic lesions at the points bitten, and both progressed to the specific rash, notwithstanding prompt arsenical treatment The biter had been under treatment with neo-arsphenamin for several months at the time

*Incomplete Form of Scurvy in Children L Wimmer —p 304
*Familial Ichthyosis M Valabrega —p 312

Hebra's Prurigo in Inherited Syphilis —Guerrero reports two cases in children of 3½ and 6 cured by specific treatment for the inherited syphilis The prurigo in both had been refractory to all kinds of local measures for months and years, and even to vaccine therapy but it subsided in a few days under mercurial treatment The clue in one case was first given by evidences of inherited syphilis in another child in the family The cure has been complete during the year to date

Purpura in Pneumococcus Infection —Bazin reports two cases in which purpura developed in infants with pneumococci in the blood He summarizes further seven similar cases from the records All were fatal

Incomplete Form of Scurvy—Wimmer refers to a condition with punctate petechial hemorrhages which he has observed in a number of improperly fed young infants He ascribes it to abortive scurvy rather than to purpura As the food is corrected the condition returns to normal Its rapid development and equally rapid subsidence confirm this assumption of its nature

Familial Ichthyosis—In the family tree reproduced by Valabrega, there are four men and three boys with ichthyosis in three generations He gives illustrations of two of the children

*The Inheritance of Syphilis J Palacio and A Moral —p 624
Improved Technic for Gastro-Enterostomy R Rodriguez Villegas —p 641
Classification of Purpura L K Wimmer —p 643

Colectomy for Chronic Stasis—The woman of 58 had a movable right kidney, and her symptoms had long been ascribed to this, but they all subsided after the portion of the colon that had been bound down by the membranes had been resected The membranes themselves had been resected at an operation five months before, but the intestine had been too much deformed to recuperate There was no shock from the extensive colectomy

The Inheritance of Syphilis—Palacio and Moral ascribe the transmission of syphilis exclusively to the mother The father transmits it only through the mother, and affects the child only through the dystrophia of the spermatozoa When the mother is infected, the child is always infected and vice versa Latent tertiary syphilis in both parents induces dystrophia of the reproductive elements, but the disease is liable to flare up under the influence of gestation in which case the child is liable to have congenital infection as well

Resection of Large Intestine—From the experiences at the time and later in 43 operative cases of cancer of the large intestine Hartert has been impressed with the absolute necessity for preventing any soiling of the tissues with fecal matter at any stage of the operation or operations With end-to-end suture, moderate invagination of the afferent in the efferent stump materially strengthens the suture The relative stenosis entailed is transient In Korte's compilation in 1913 of 434 radical operations for cancer of the large intestine 61 3 per cent survived the operation and 38 3 per cent of the survivors were free from recurrence for over three years that is, 23 5 per cent of the total 434 patients were cured for three years at least The corresponding figures in Hartert's group of 28 surviving of his 42 cases in Perthes service show that 39 1 per cent of the 23 traced to date are still free from recurrence for three up to ten years There were no operative fatalities in the 14 cases in which the resection occurred without soiling with feces, either at the main operation or the succeeding ones To insure asepsis in making a fecal fistula he sutures the serous membrane of the bowel to the edges of the incision in the skin with as much care as for an intraperitoneal suture of the bowel He also covers the suture with a paste and introduces a fistula apron of impermeable tissue, the edges sutured tight to the bowel serosa He refrains from suturing the bowel to the parietal peritoneum, fearing further manipulations He prefers a jet of steam for sterilization of the intestine content but warns against the excessive use of this or of antiseptics Resection at one sitting is preferable for cancer of the large intestine not only when there are no complications but also when there is ileus so long as peristalsis is vigorous. Several pages of bibliography are given

Noncarcinomatous Gastric Tumors—Dessecker advocates pneumoperitoneum as a last resource in the differential diagnosis of a nonmalignant tumor on the outside or inside of the stomach Tumors in the stomach wall and solitary polyps are beyond our differentiating skill An exogastric tumor is liable to pull the stomach out of shape The funnel-like protrusion of the stomach wall into the pedicle of the tumor is characteristic as also the smooth outline of the endogastric growths and their movability on palpation during radioscopy with the stomach of normal shape He illustrates a case in which a segment of the stomach was resected containing a fibroma as large as a hen's egg with ulceration at three points The few cases on record of myoma, fibroma solitary polyps etc are compared with this case, and he adds that there are about 200 cases of primary gastric sarcoma known He cites 3 cases in which the sarcoma had developed on the exterior of the stomach

Peptic Jejunal Ulcer—Haberer's experience condemns exclusion pyloroplasty as inviting peptic ulcer, although the latter may follow gastro-enterostomy alone The first Billroth method seems the safest for operative treatment of the stomach from this and other standpoints The diet must be strictly regulated after any operation on the stomach, he does not allow solid food for two weeks A peptic ulcer may recur in operating for this the resection should be on the same principle as the first Billroth method He gives the details of 26 cases of peptic jejunal ulcer treated by radical resection In 2 cases the ulcer was a recurrence The primary lesion had been in the duodenum in 23 cases and in the pylorus in 8 Pyloroplasty had been done in 18 of the total cases in the others intervention had been restricted to posterior gastro-enterostomy A jejunal peptic ulcer never was observed after any of his own 865 cases of resection of stomach or duodenum but there were 12 instances of it in his 71 cases with exclusion of the pylorus, and in 3 of his 275 gastro enterostomy cases

Regeneration of Bone Marrow in Pernicious Anemia—Walterhofer and Schramm reported a few months ago the favorable influence on the course of pernicious anemia observed when part of the marrow of one tibia or femur was

scooped out Four of the nine patients thus treated have died since, and they here describe the regeneration of the marrow observed in these four fatal cases Death had occurred from secondary infection in two The regeneration process seemed to correspond to what is observed experimentally in healthy dogs, only that it occurs more slowly, probably on account of the age There does not seem to be any anatomic insufficiency of the bone marrow in pernicious anemia The favorable influence from the operation is evidently due to the stimulation of the bone marrow therefrom, and the perpetuation of this stimulation by the regeneration

Injection of Antiseptics into Joints—The experiments on fifty rabbits warn against prophylactic injection of strong antiseptics into joints

Traumatic Spinal Affections—Gocke reviews the ultimate outcome in fifty-five cases of injury of the spine, with or without nervous symptoms This experience has convinced him that Schanz' insufficientia vertebrae is based on mistaken premises, but it has served to deepen our knowledge of disease of the spine

Operations in the Posterior Cranial Fossae—Mintz remarks that scarcely anywhere else is there such an accumulation of unfavorable factors as in operations on a posterior cranial fossa And yet he is able to report cures in 25 per cent of twenty-six cases of a tumor in this region (16), cysts in or below the cerebellum a hydatid cyst (3) or serous meningitis Postoperative hydrocephalus is liable to stretch the tissues and tear open the scar This is the usual cause of the insidious meningitis after operations in the region

Vertebral Sarcomas—Guleke describes three cases of hour-glass tumors in the spine which grew through the intervertebral openings and spread out in the muscles and spaces beyond The portion in the muscle tissue may grow very large, but these fibrosarcomas develop slowly and seem to be comparatively benign for a long period Operative measures have every chance for success He illustrates his three cases and describes the preferable mode of access One of his patients, a farmer, now 30, was operated on nine years ago, and has been free from all disturbances since One boy of 11 succumbed to secondary infection from a fistula, and a young woman to infection of a hemopneumothorax that had followed the removal of the tumor All the patients bore the operation well

Atresia of Anus and Rectum—Oppel operated on the otherwise normal and vigorous new-born child by cutting the anus on each side and extending these incisions The blind stump of the rectum lay 3 cm above, and this was mobilized through an abdominal incision, and was then sutured to the posterior half of the anus Through the anterior half, tampons were introduced separate from the rectum The tampons were gradually removed and clinically normal conditions were restored in time

Ulcers of the Lips and of the Mouth Cavity Ledderhose—p 527
Technic of Treatment of Gonorrhea M Joseph—p 529

Quantitative Test for Occult Blood—Gattner and Schlesinger have found that the reaction to benzidin strictly parallels the quantity of blood present, from the largest to the minutest amounts, even with occult hemorrhage The tint durability and sensitivity are directly proportional to the amount of blood in the fluid With a set of tubes and serial dilution it is possible not only to detect the occult blood in the stool but to determine whether it is increasing or diminishing from day to day They describe the exact technic they have found most convenient for this

Feeding Through the Nose by Drip Method—Samson and Baare relate that they have tided new-born infants with pylorospasm along by this means until the spasm subsided, and the infant came out from under it without the usual signs of inanition When the infant lies quietly, the tube can be left continuously in the nose, fastened to the brow and cheek with a couple of strips of adhesive plaster When it is restless, the tube has to be withdrawn and replaced at need They found human milk the best to use for this drip feeding, and report two cases in detail The absence of sucking and vomiting movements and of overfilling of the stomach does away with some of the factors inciting to vomiting, and thus aids in overcoming the tendency to spasm This drip method might be used for duodenal feeding, and supplying water

Removal of Pigmentations of the Skin—Kromayer describes a method of removing freckles, small nevi, liver-spots, etc The object is to remove the epidermis and along with it the pigment-bearing epithelia without injuring the cutis propria The method is adapted from dental technic According to the size of the blemish, the tissues are frozen or infiltration anesthesia (procain, in a 1 150 or 1 200 solution) is employed A burr of the proper size is chosen and is rotated in the same manner as in dental technic The teeth or edges of the burr seize hold of the tissues of the epidermis and the cutis vasculosa, whereas the cutis propria, which should be spared in order to avoid scar formation, is left intact unless strong pressure is applied It is well to begin at the lower end of the field and work upward When hemorrhage and serous transudation following the operation, have ceased, the wound surface is covered with a very thin layer of cotton fibers which stick to the wound surface, dry, and form an artificial scab In from ten to fourteen days (earlier, if the defect is small) the scab drops off The site is red at first but after two months all trace of the operation has disappeared The method is excellent for large liver-spots

Deutsche Zeitschrift fur Chirurgie, Leipzig

April 1922 **170** No 1 4

*Diphtheria of the Esophagus W Stupka—p 1
Appendicitis in Hernial Sac E Otto—p 53

*Blood Pressure During Local Anesthesia O Wiemann—p 150
*Reconstruction of Face A Lindemann—p 182
*Treatment of Inflammation R Eden—p 209
*Wound Diphtheria Hilgenreiner—p 266

Diphtheria of the Esophagus—Stupka tabulates the details of 34 cases of fatal diphtheria of the esophagus, published by 24 writers in the course of a century He also tabulates 9 cases of postdiphtheric stenosis, and describes with roentgenograms 2 cases in his own experience In 4 of the total 11 cases the stenosis was multiple One patient was a new-born child, the oldest was a woman of 42 Dysphagia is the most common and important symptom, but it is usually ascribed to the throat process Expulsion of a cast of the esophagus was observed in 5 cases, but as a rule diphtheria of the esophagus escapes detection There is ulceration at first and then cicatricial stenosis in the course of two or three months Measures to prevent development of stenosis should be applied early A retention sound has been applied with excellent effect by three clinicians lately, to ward off stenosis after swallowing a caustic and he suggests the possible advisability of this with diphtheria involving the esophagus It is especially advisable here as the ulcerative process with true diphtheria does not burrow deep

Fibrous Osteitis—Sauer's discussion is based on twelve cases, all but one in girls or women

Blood Pressure During Local Anesthesia—Wiemann reports from Konig's service research on the blood pressure and the pulse during and after procain-epinephrin anesthesia

Reconstruction of Parts of the Face—Lindemann is chief of the *Kieferklinik* at Dusseldorf, and describes correction of some unusually grave war disfigurements of the face

Physical Chemistry in Treatment of Inflammation—Eden analyzes the various phases of an inflammatory process, and explains how treatment must vary to meet these different phases Hyperemia must be stimulated in one phase and checked in another He ascribes great importance to the protecting action of a coating of fibrin on recent wounds and granulations He emphasizes that none of the disinfectants proposed to date answer surgical requirements Test tube experiments and experiments on animals are no criterion of the action on living tissue The manifold peculiarities of clinical conditions cannot be reproduced in vitro nor in animals The search for the ideal disinfectant, he says, should be along the lines of research on ions and the laws of molecular absorption and dispersion the chemistry of colloids, and the effect on bacteria of modifications in osmotic tension Colon bacteria, for example, disintegrated when transferred from a 0 75 to a 2 per cent saline, although the latter is not strong enough to be bactericidal Colon bacillus infection of the urinary apparatus has responded very favorably in his experience to treatment with 20 per cent solutions of sugar

Wound Diphtheria—Hilgenreiner's experience suggests the wisdom of examining the secretion for diphtheria bacilli when a wound does not heal properly There may be nothing to suggest diphtheria otherwise. In a case described, the relics of an abscess in the breast refused to heal for four months until they finally yielded to a mercurial salve All kinds of treatment had been applied to no avail before

Recent Literature on Public Health H Ziemann—p 606

Treatment of Diphtheria—Friedemann insists that his experience with 4,000 cases of diphtheria in the last seven years has demonstrated that successful treatment is merely a question of the dose of antitoxin in the overwhelming majority of cases The difference between the effect of large and small doses was most striking in the edematous form of diphtheria His statistics from various German and Austrian hospitals show a death rate from this disease from 11 7 to 15 2 per cent since 1914, while Friedemann had only a death rate of 6 per cent in 3,421 cases, and only 4 3 per cent in the cases treated with 20,000 units In two cases of the severest necrotic type, the children recovered under a total of 60,000-90 000 units

Serodiagnosis from Blister Fluid—Buschke remarks that the serum in a cantharides plaster blister responds to the Wassermann and the tuberculin tests like the blood serum but with less intensity The assumption is gaining ground more and more that the skin is an organ with an internal secretion and plays an important part in the production of defensive substances This is evidenced, among other things he says, by the more generally favorable course of syphilis when a rash develops under mercurial or arsenical treatment

Leukocytosis Therapy—Fischer thus designates what others call protein therapy, and he explains its action as inducing the flaring up of inflammatory processes His reports on the use of sodium nucleinate for this purpose in general paresis have been summarized recently (June 10, 1922, p 1855)

Influence of Disease on Epinephrin Production—Peiser reports contradictory findings in regard to the epinephrin content of the blood in various diseases Only in 9 cases of peritonitis was it constantly low—down to 1 73 mg—in 88 89 per cent In tuberculosis it was usually within normal range as also in 12 cases of carcinoma, and one each of sarcoma and actinomycosis The only other constant finding was an increase of almost 50 per cent in all the 11 cases of valvular defect instead of the average 3 05 it was 4 78 mg

Traumatic Neuroses—The official report on two cases is explained and amplified

Obstetrics Without Vaginal Examination—Kupferberg comments that further measures will have to be devised to combat the increasing number of cases of puerperal fever They have doubled in the last five years, although the number of births has declined As a step in the right direction, he urges that the vaginal examination should be done two or three weeks before term, and after this, no further internal examination or procedures should be allowed until eight days after delivery, except by the rectum For this the forefinger in a rubber cot is covered with a square cloth the size of a handkerchief, with a 2 cm slit in the center, through which the finger is slipped By this means the finger is protected against soiling The cloth can be dipped in an antiseptic If the hard skull bones fontanels and sutures cannot be felt through the rectum then face, shoulder or breech presentation is obvious, and further differentiation is easy from without He warns against mistaking the sinking pains late in pregnancy for labor contractions, reporting two cases in which after two and three days of alleged labor pains, forceps was applied or the cervix slit in four places In both cases the cervix had not opened—as might have been ascertained by rectal examination The slit had been made in a fold in the vagina wall, and the forceps had been applied to the head capped entirely by the uterus wall, stretched to its utmost. The mistake was recognized in time in both cases A number of minor points to aid in delivery are enumerated

Menstrual Disturbances with Pulmonary Disease—Guth has noticed that the course of pulmonary tuberculosis was generally favorable when the menstrual periods were long

and free from premenstrual rise in temperature When a previously long period became shorter, this was a sign of improvement or acute exacerbation When the menstrual period was not modified either way, the disease seemed to be a recent infection, and the course was less favorable A period of less than three days was found only with anemia or chlorosis, and there was generally dysmenorrhea

Ascaridiasis—The girl of 11 died in twenty-four hours with symptoms of peritonitis plus ileus, explained by obstructing clumps of ascarids—60 in all—and corresponding toxic injury of the mucous membrane In a second case, in a girl of 4, the toxic injury was more insidious, and the previously robust child died in two weeks from increasing weakness and heart failure

Importance of the Blood Pressure in Obstetrics—De Snoo combats high blood pressure in the pregnant by repose and dieting He regards the course of the blood pressure as a better index of conditions than albuminuria If the pressure drops to normal, the intoxication can be regarded as being at an end for the time being In eclampsia, the high blood pressure is evidently a means of defense although it brings danger of convulsions, exhaustion of the heart, cerebral hemorrhage, etc Every woman with a high blood pressure should keep quiet during the last months of pregnancy whether there are any symptoms or not Systematic examination of the blood pressure is indispensable during pregnancy 'It is the compass with which we often can steer the frailest bark into the harbor of safety" He has never known a case of eclampsia or impending eclampsia without high blood pressure With this we can distinguish eclampsia from hysteria, brain tumors, epilepsy, etc

Pruritus as Symptom of Polyglandular Insufficiency—Szondi and Haas state that of ten patients suffering from essential pruritus which did not respond to the usual dermatologic treatment they found in six cases typical pluriglandular insufficiency, and in the remaining four patients there was dysfunction of at least two endocrine glands The changes of the genital glands, which other writers mention in connection with pruritus, are only partial manifestations of the pluriglandular insufficiency In their cases the pruritus was merely a manifestation of endocrine dysfunction plus hypersensibility of the peripheral sensory nerves The latter was caused by pathologic metabolism products entering the blood stream on account of the dysfunction of the endocrine glands The hypersensibility exists latent in the whole region of the peripheral sensory nervous system and will manifest itself in the form of itching where there is constant or frequent irritation An endogenous and an exogenous factor are thus necessary The endogenous factor consists of a definite constitutional or acquired abnormality of the endocrine system The most frequent exogenous factors are fluor, nodes, onanism, rubbing of the collar, etc The exogenous factor does not bring about the chronic itching except as the above-mentioned constitutional or acquired basis is present Causal treatment has not so far been able to effect permanent improvement In stubborn cases roentgen irradiation is recommended as symptomatic treatment

*Dystrophia of Veins in Infants E Slawik—p 322
Esophagus Cyst in New Born Child Buttenwieser—p 352

Amount of Nourishment Required by Underweight Infants—Ambrozic compared the Heubner and the Pirquet systems for estimating the amount of nourishment needed by infants notably under weight His conclusion is that the amounts should be like those for normal infants of the same length, rather than computed by age or weight

The Chlorids in Infant's Blood—Salomon's tests on infants have confirmed that the chlorid content of the blood sinks while digestion is proceeding in the stomach Fat-rich food forms an exception to this rule, and he theorizes to explain the reason for this

Fulminating Purpura in Infant—The apparently healthy infant of 19 months died in two days after the onset of the

purpura Streptococci were cultivated from the blood and a positive Wassermann was also obtained

The Bone Marrow and the Blood Picture in Relation to Aplastic Anemia—Hummel relates that the patient, a boy of 12, belonged to a healthy family He succumbed to sepsis from infectious purpura after months of aplastic anemia Notwithstanding the blood findings indicating chronic aplastic anemia, necropsy revealed that the blood marrow was hyperplastic, abounding in leukocytes and eosinophil myelocytes, although the proportion of erythrocytes was small and there were few nucleated erythrocytes The case emphasizes that in study of anemias we must discriminate between the two functions of the bone marrow the production of blood corpuscles and the delivery of them to the blood stream Possibly puncture of the marrow, as Ghedini suggests, may prove instructive

Acute Yellow Atrophy of the Liver in Child—An apparently harmless jaundice in the boy of 3½ suddenly assumed a fulminating form The case confirms the assumption that occult gastro-intestinal infection may induce a catarrhal jaundice which may progress to acute atrophy of the liver

The Skull of the Prematurely Born—Rosenstern's tables confirm that the frontal fontanel is smaller the more premature the birth, and other anomalies were noted in the skulls of the thirty-eight prematurely born infants studied

The Physical Properties of Foods in Infant Feeding—Rosenstern and Lauter emphasize the importance of the form of the solution in infant feeding, presenting evidence that the scale of dispersion of the elements of the food, rather than its chemical composition, may be of decisive import in its action on the bowel In this preliminary report of their research on the different behavior of crystalloids colloids suspensions and emulsions, they show that colloids and fine suspensions seem to check diarrhea Albumin checks diarrhea both by its physical and its chemical properties while sugar both physically and chemically, promotes diarrhea The physical properties may be the explanation for the favorable action of albumin milk and buttermilk

Defective Development of Veins in Infants—Slawik reports clinical observations and histologic and experimental study of dystrophia of veins in infants He never encountered any actual varicose enlargement of the vessels in infants In one child the sequence was dystrophia of the veins in early infancy, then vasomotor instability, livid discolorations of the skin, and, later, dilatation of the left heart

Modified Operation for Varicocele A Gregory—p 369

Abortive Treatment of Erysipelas—To check the spread of the initially localized disease and if possible to bring it to a standstill, Kumaris uses a small thermocautery, with which he performs a punctiform cauterization of the entire skin surface involved, at one sitting if necessary, under light anesthesia By thus thoroughly opening up the affected area, with the resulting hyperemia he endeavors to prevent the migration of streptococci or their injurious action on the organism In recent years he has treated five cases thus and the result was excellent in every case The infection was brought directly to a standstill The following morning the temperature ranged from 36 5 to 37 C and remained normal, the treated area was, for the most part, pale It was not in any case necessary to repeat the cauterization, there being no refractory areas and no extension of the affected area Refractory areas are prevented by covering very carefully the whole affected area, leaving no islands not cauterized Extension of the affection is prevented by cauterizing for from 1 to 2 cm beyond the borders of the erysipelas The parts affected were the gluteal region the thigh, the lower leg and the whole leg The last case presented a high fever, continual vomiting and stupor, the reddening spreading over the whole leg within forty-eight hours The leg was cauterized under light anesthesia, from the iliac crest down to the toes The result was astonishing The patient, who had been feeling wretched the evening before, was sitting up the next morning feeling perfectly well, with a temperature of 37 1 C

Division of Work in the Ovary—Guggisberg has been trying a new mode of experimentation to throw light on the problem of division of work in the ovary He has reached the definite conclusion that the Graafian follicles must be recognized as producing an internal secretion His investigations lead him also to believe that there is no sharp division between internal and external secretion in the ovary, as has been maintained by some writers

Zentralblatt fur innere Medizin, Leipzig

March 11 1922 **43**, No. 10

*Blood Pressure in Relation to Diabetes. G Marañon (Madrid)—p 169

High Blood Pressure in Relation to Diabetes—Marañon regards the relation between high blood pressure and diabetes as very important but also as very obscure as yet His statements are based on 90 recently observed cases of diabetes He found the same as Kylin that when the diabetes occurred at a more advanced age arterial hypertonia was more common and more intense The question is, Does this express a causal relation or a mere coincidence? A systematic study of blood pressure in healthy persons 40 years old and upward shows a constant increase of pressure However, if we examine carefully the course of the arterial pressure and the diabetes in these cases it appears evident that in a considerable number of patients there occurs a period of arterial hypertonia for a variable length of time before the appearance of glycosuria and other clinical signs of diabetes When glycosuria finally appears it often happens that the hypertonia continues for several years and then decreases In the 90 cases mentioned he observed that, as a general thing, the high blood pressure decreased in proportion as the patient got farther away from the clinical onset of the diabetes Certain cases of hypertonia without glycosuria develop later into genuine diabetes Among those who, at about the age of 40, begin to show signs of high blood pressure there are a few in whom the development of a diabetic condition seems

likely In these there will be a more or less marked increase of blood sugar, a decrease of the carbohydrate tolerance, intense circulatory and nervous reaction to injection of epinephrin, and in certain cases the appearance of signs of a diabetic diathesis Of 22 cases of hypertonia without glycosuria he found hyperglycemia present in 14, or 63 per cent, which agrees with the findings of Hagelberg, Farini, and Williams and Humphrey, though opposed to Kylin's statistics Kylin found hyperglycemia only once in 15 patients with hypertonia

Acute Meningitis—Herderschee states that there was no headache in 4 of his 82 cases of suppurative meningitis, no stiffness of the neck in 5, and no Kernig sign in 16 There was no headache in 6 of his 108 cases of tuberculous meningitis All died of the 17 in which the pneumococcus was found in the spinal fluid, also in the 4 streptococcus cases, and the one case with both the pneumococcus and the streptococcus, also in the one case with colon bacilli, and the one with *Diplococcus crassus* Only 3 died of the 8 with no micro-organisms found, and 31 of the 68 with meningococci One patient was left blind, another died two weeks after apparent recovery, and necropsy revealed unsuspected hydrocephalus Among 539 feebleminded in a Norwegian institution, 3 per cent were known to have had meningitis Ten Doesschate found disturbances of various kinds in 48 of 180 soldiers who had had epidemic meningitis from two to thirty-one months before, 54 had died In Herderschee's 108 cases of tuberculous meningitis, in 24 the hearing was impaired, 25 had nystagmus, 7, changes in the choroid and only a few were free from pains in head or back, early fatigue, etc Ptosis was noted in 42 per cent of the cases of tuberculous meningitis, strabismus in 53 per cent and anisocoria in 55 per cent In other forms of meningitis the corresponding proportions were *16, 23 and 29 The onset* was sudden in 5 per cent of his tuberculous cases, and in 53 per cent of the nontuberculous In one of the latter the apparently healthy boy came home from school at noon with headache, saying that the teacher had boxed his ears The boy died the same evening, and necropsy revealed the meningococcus meningitis

Asthma as a Nasal Reflex Neurosis—Henkes found abnormal conditions in the nose in all but one in a series of 12 cases of asthma of recent development and also in 40 of 48 cases of asthma of long standing In these 51 cases, the electric current applied to the middle turbinate bone induced a kind of wheezing sound in the breathing, and breathing became more difficult With pathologic conditions in the nose and pharynx, if this electric test is negative, the cause of the asthma must be sought elsewhere But if the test is positive, then treatment of the nose, pharynx or some sinus *is indicated* Insidious suppuration in the ethmoid cells is particularly liable to be responsible for this form of asthma He reports a case in which the asthma subsided permanently after the clearing out and healing of an abscess in the middle turbinate In families in which there seems to be a predisposition to asthma, he has seen the older children develop at times a difficulty in breathing, ascribed usually to nervousness He is convinced that this is the precursor of actual asthma, a sign of a pathologic reflex route from some anomaly in the nose In three children of this type the anomaly proved to be adenoids, or an inflammatory process in the nasal mucosa, or unsuspected suppuration in the ethmoid sinus All three had reacted with wheezing to the electric test, and none have displayed any respiratory disturbance since the cure of these processes He applied for the test a weak faradic current through an oval metal plate with an area of about 0 25 sq cm , the other electrode at the back of the neck In practice this test is seldom necessary It is enough to treat any abnormal conditions found If the asthma does not subside under this, then this electric wheezing test will reveal whether the cause is elsewhere, or more careful search should be made for it in nose and sinuses

Proprietaries Versus Official Drugs—Molema as a country physician is obliged to dispense his own medicines, and he has been impressed anew of late with the difference in price between the proprietaries and the pharmacopeial drugs He gives a list of ten of the more commonly used proprietaries with their wholesale prices, 10 kg totaling 573 florins, while the same amounts of their pharmacopeial equivalents total less than 160 florins He declares that the physician while guarding the health and strength of his patients should also guard their material interests

*Ileus as a Consequence of Certain Congenital Anomalies E Dahl Iversen —p 189 Concn No 15

Ileus from Congenital Anomalies—Iversen does not include in this study atresia of anus or rectum, diaphragmatic hernia and diverticulum of the ileum He has compiled 36 cases observed in Denmark, 4 were encountered in his service in a two year period In 2 of these there was volvulus of the small intestine, in another there was multiple atresia of the small intestine, and in the fourth, a fibrous band bound down the duodenum This last child seemed to have been cured by the excision of this band, but after a week of progressive improvement the vital functions seemed to flag and the infant died from inanition The operative shock or the narcosis may have been responsible for this, notwithstanding the interval of a week of improvement He gives the details of the Danish cases, and notes the symptoms that point to the site of the obstruction The ileus may not develop for several weeks or months after birth or not until some cow's milk clot or chunk of food obstructs the previously permeable stenosis One infant with green vomiting from birth recovered after entero-anastomosis to exclude the infrapapillary portion of the duodenum, the seat of atresia This male child has developed normally during the six years since He knows of only 3 other cases in international literature of successful operations on infants for ileus from congenital anomalies Entero anastomosis had been done in 2 and an obstructing band severed in the others In 7 of the Danish cases the ileus did not develop until the age of 3 up to 56 years

THE FUNDAMENTAL PRINCIPLES OF ORTHOPEDIC, RECONSTRUCTION AND INDUSTRIAL SURGERY

THE REAL LESSONS OF THE WORLD WAR*

H WINNETT ORR, M D
LINCOLN, NEB

In this section we should remember that in 1916 Col Joel E Goldthwait and four other members, Hibbs, Henderson, Osgood and Allison, were appointed a committee on preparedness to arrange for our participation as orthopedic surgeons if the United States became engaged in the World War Our attitude then was one of high idealism, we were prepared to offer time, effort and even life if necessary, in the service of our country and our countrymen

It is now a matter of history that the opportunity came, and that, in the spirit suggested above, Colonel Goldthwait and his associates made exactly the offer and the effort that was expected of them [1]

Now, however, if we attempt to discuss the results of that effort, in the spirit of today, we are very likely to develop a tone that differs greatly from that which was used in 1916 There are those who not only disparage the effort, but who deny the patriotism of those who engaged in the orthopedic part of our campaign against the belligerent Central Powers There are also those who contend that the final victory of the Allies has brought us no good results of any kind In fact, there is so much confusion in politics and international policies, and in the affairs of the world in general, that it is difficult to discuss even questions of service and scientific progress and separate them, for special study, from other national and world affairs that are clamoring for attention

This puzzled and uncertain or even negative attitude is, perhaps, not entirely unreasonable It is difficult for one to devote oneself wholeheartedly to the solution of problems of surgical procedure and methods of physical reconstruction for his patients, when the surgeon himself is trying to rehabilitate after a period of military service Moreover, the situation is complicated when the soldier patient is more concerned about securing a cash bonus or compensation than he is about getting well

All of these things have a bearing upon the topic which I have selected for my address I feel that, with a little time for consideration, we can arrive at fairly definite conclusions as to some of the lessons learned from the war

FIRST PRINCIPLES

Our Surgeon General has said recently that the surgery of the war consisted chiefly in a "harking back to first principles" [2] This comment may or may not do justice to our two years of effort in the military service One might say that, if we really had successfully "harked back" to first principles, we might feel fairly well satisfied with the achievement After all, compliance with first principles is one of the things that surgeons have not done too well It does seem to me however, that this comment calls for both elaboration and explanation if we, as surgeons, are to get anything for our patients and ourselves out of our war experience

There were during the war certain occurrences in the surgical services that represented serious aberrations, if we consider them from the standpoint of first principles

Our concern, as orthopedic surgeons, has been chiefly with the prevention and correction of deformity, and with the restoring to useful citizenship of those who suffered by reason of the military service

Have we as surgeons learned anything new or profited in any way by our service in the hospitals in Great Britain, in France or in the United States?

I believe that it may be said that the character of such work is better at the present time than it was five years ago, and that it is better because of certain lessons learned in the army hospitals

Orthopedic or reconstruction surgery in this country is still very poorly done We have still many thousands of children and industrial workers who are crippled deformed and physically handicapped because of inadequate medical and surgical attention There are as yet insufficient hospitals We lack special training schools for selected vocations for the crippled, and there is even now no real public or even professional conception of what may be done in the prevention and cure of deformity, the relief of disability, and the retraining of the physically handicapped

To illustrate If only the splinting of fractures and infantile paralysis were promptly and properly done in the United States, the total amount of crippling and serious disability would be reduced by about 10 per cent Or if suitable measures were appreciated and encouraged by physicians to prevent and relieve foot strain, foot pronation and acquired foot deformities, another 15 to 20 per cent of our partially or totally disabled workers could be made more comfortable and more efficient With regard to the latter cases alone, Colonel Goldthwait's special training battalions in France furnished a lesson from which every city in

* Chairman's address read before the Section on Orthopedic Surgery at the Seventy Third Annual Session of the American Medical Association St Louis May 1922

1 Report of Committee on Orthopedic Preparedness Tr Sec Orthop Surg A M A 1917 p 248

2 Garrison F H History of Medicine Ed 3 Philadelphia W B Saunders Company 1921

this country could profit if the message were carried by our orthopedic surgeons and the other members of the medical profession

LESSONS FROM VARIOUS PROCEDURES

The war taught us that much disability and deformity may be prevented by adequate first aid treatment Our experience in this regard, though less extensive, was just as convincing as the prophylaxis that succeeded so well in typhoid fever and tetanus It is only necessary to refer here, by way of illustration, to the saving of life and limb that was accomplished by the application of the Thomas splint in compound injuries of the femur, by splint teams on the battlefield The results achieved by this one procedure should be sufficient reason for placing Thomas splints and splint teams at every point in America where such accidents are likely to occur As it is, there are already hundreds of places where a Thomas splint had never been seen before, where there are now adequate provisions for the immediate splinting of such injuries

This section should acknowledge, as one of the outstanding achievements of the war the results of the labors of Goldthwait, Allison, Osgood, and Baer, in the simplification and standardization of splints and splint methods In this respect, at least, we caught step and I think even went ahead of our allies We are now certainly getting better results than formerly in the care of many industrial accident cases I believe that these results are due more largely to the earlier and better application of splints than to any other cause

In any discussion of progress in war surgery one of the first topics to be suggested is that of the Carrel-Dakin treatment of infected wounds The results of such wound treatment in a few instances were such as to give the whole subject almost an atmosphere of romance The rapid and obvious reduction in infection, the diminishing number of septic organisms, the improvement of the patient's general condition, and finally even the secondary closure of certain wounds made a strong appeal, both to patient and surgeon I believe I can say, however, that out of these very experiences we should get one of the important lessons of the war The field of application of the Carrel-Dakin method has already been fairly well realized and we shall admit without argument that the method has a certain, if limited, value

My principal point, however, from the standpoint of an orthopedic surgeon, is that neither the Carrel-Dakin method nor any other kind of wound treatment should be permitted to interfere seriously with the fundamental principles in the treatment of bone and joint injuries Those principles are, first, the immediate replacement, as nearly as possible, of injured parts in anatomic relationship, and second, the maintenance of immobilization ("enforced, uninterrupted, and prolonged"—Hugh Owen Thomas) of such injured parts in proper relationship until healing occurs

In other words, wound treatment of whatever kind must not interfere with splinting in correct position In the application of the Carrel-Dakin method, the disturbance of splints and the discarding of casts has been very common It is my belief that splinting should come first in compound injuries, just as it should in infantile paralysis In infantile paralysis, massage, electricity, manipulations, hydrotherapy and all other measures of physiotherapy are of secondary and minor importance as compared with splinting in correct position My attitude with regard to the Carrel-Dakin or any other forms of wound treatment (except drainage) in compound injuries is exactly the same, that is, they are secondary to correct splinting

This argument also brings up the old question as to splinting and stiff joints To this my answer is that stiffness, whether of the joint itself or of the adjacent soft parts, is due not to immobilization but to pathologic changes Such changes are always due to irritation, inflammation, tissue destruction and scar formation All of these are kept at a minimum, not by movement, but by rest The minor stiffness that is inevitable to the minor injury can be broken up after healing occurs The more serious stiffness that results from more serious injury cannot be broken up either at the time by poor splinting or by force later on

Another important war experience, and one which attracted much attention at the time, had to do with the so-called Willems method of the treatment of infected joints by keeping them in motion Accurate and careful adherence to the exact technic promulgated by Willems surely gave, and will give, good results in some acute septic joints (Careful splinting and sound healing will give the same results or better) On the other hand, experience taught us the great danger of keeping infected joints moving under any except ideal conditions I saw during the war, and have seen since, many cases of serious disability and severe deformity in which attempts were made to maintain motion in joint cases, which should have been protected and allowed to become stiff in better position

Even from one of the most brilliant procedures that came out of the surgery of the war—debridement—there are negative as well as positive lessons to be learned Certainly we saw that lives and limbs were saved by the early and complete removal of badly damaged and infected tissues That such procedures should be done only by skilled surgeons, however, is attested by the frequency with which principal peripheral nerves were sacrificed and serious disabilities resulted owing to bony and soft part defects

OCCUPATION OF DISABLED

One of the greatest lessons of the war is one in regard to which we, as a profession still have much to learn This is the lesson of the occupation of the sick and disabled Both in the army and out of it, we are still pursuing, with regard to our disabled, a policy which in many cases is bad for them and bad for us

This is the policy of compensation without directed or supervised employment It is true that we have a fairly elaborate machine set up for the vocational guidance and for the employment of our crippled discharged soldiers For our industrial cripples there is almost no provision whatever The fault now is not so much with the governmental agencies as it is with the general public and with the profession The employment of the idle presents a problem for the solution of which the intelligent cooperation of the entire community is necessary As long as idleness is permitted, and especially as long as it is encouraged, we shall have the problem of the unemployed, either lame or well Certainly, however, in institutions in which supervision is at hand, every inmate should be engaged, if possible, in some sort of useful occupation These occupations can be made educational and instructive as well as

remunerative and curative Then the individual will be on the way to real rehabilitation, socially as well as physically

We have passed, have we not, that period in human history in which power and possession were yielded to that one who was physically the strongest? We are supposed to have now a government which guarantees to us all equal rights for the enjoyment of life, liberty and the pursuit of happiness Are we not perhaps ready for the next step forward into an era in which, by common consent, we may give special opportunities, special privileges and special facilities for self help (instead of merely charity) to those who cannot—mentally or physically—keep up under the strain of competition with those who are fit?

CONSULTATION AND SUPERVISION

In spite of the arguments of those who fear and object to paternalism, I wish to say a word from our experience with the supervising consultant in the military hospitals It is an idea which remained firmly rooted in our surgeons, even after they became medical officers in the United States Army, that the hospital service and the patient assigned to any one became more or less his personal property One needs only to see the attitude of any surgeon now toward his hospital service and his hospital patients to find out how quickly he resents supervision, direction or even suggestions as to the care of his patients If any attempt is made to direct the care of any patient apart from the surgeon's invitation, he is at once affronted This feeling must, of course, rest on the assumption that the surgeon knows so much about his work that no one can tell him anything

Would it not be better for our patients to meet this question fairly and allow methods of treatment to be checked up by those who are competent to give an expert opinion?

In the military service, we certainly found hospitals surgical services and wards in which specially trained consultants were able to contribute much to the work that was being done I believe that it may be said that this is particularly true of consultants in orthopedic surgery At any rate, in orthopedic surgery, it was particularly easy to demonstrate the results of decisions as to treatment and the supervision of the care of patients by consultants I can recall instances in which a single visit by the consultant with a tape measure to a femur fracture ward resulted in correction of deformity, lengthening of shortened limbs, and the improvement of the condition of twenty or thirty patients in a single day

That this method might be applied in the same way to present day conditions and present day hospitals, I believe no one can deny It is my belief that a consultant in orthopedic surgery with correct ideas regarding the prevention of deformity could contribute to the welfare of many patients, to the improvement of their condition, and to the prevention of some deformity, in most of the hospitals in this country

I am not unaware of the objections to further inspection,' consultation and supervision by city, county or state officials of any kind I have some reason to believe that this sort of thing is being overdone And yet the chief objections to consultation and supervision come from those who in a sense, create the necessity for it We have many inspectors of all kinds who are incompetent and superfluous On the other hand, we have inspectors who are responsible for the fact that we are served with healthful meat and clean milk, that we enjoy a measure of police and fire protection, that we have paved streets and good roads, and that we enjoy many other privileges and immunities

In the same way I believe that it may be said that, in spite of any objections that may be raised, systems of hospital or community consultation in fractures and other serious injuries would raise the level of such treatment and bring about an era of better results It cannot be denied that many fractures are being treated today by those without proper training, skill or experience in such work

Other disabilities and deformity-producing diseases and injuries are being handled in the same way Standards of treatment and results definitely set down, and more or less rigidly enforced, seem to me to be the only answer And for this purpose a consultation scheme with the development of something like an "orthopedic conscience" seems to be necessary

POSSIBILITIES OF REESTABLISHMENT

The experience of the war has brought to our attention very forcibly the fact that our results in this class of cases are not as good as they should be In the draft, in the army hospitals, and since the armistice we found, and do find, disability and crippling that should have been prevented We constantly find instances of avoidable deformity And there are daily opportunities to replace in society and in industry cripples who are idle now because of the neglect of treatment and training

We have had splendid illustrations in our own country as well as in Great Britain, France and Italy of the meaning and methods of rehabilitation in the broadest sense Canada has shown us in a very striking way the possibilities of "reestablishment" In all the countries of our allies, as well as our own, surgical reconstruction is being admirably done to a certain extent

Moreover, we now know that congenital and acquired deformities are equally amenable to relief if we follow the fundamental principles of orthopedic surgery And, briefly stated, these fundamental principles are, first, to restore to and secure healing of parts (at *any time* after injury) in as nearly correct anatomic relationship as possible And second, we have surely learned that there are practically no limits to the possibilities of reestablishment of the individual by the educational and training development of original compensatory or vicarious functions

---

Fighting the Drug Menace—The League of Nations recently held a conference in Geneva on opium, and Congress has passed a bill limiting the importation of drugs The medical societies are also assisting in the crusade by endeavoring to eliminate those who profess to be curing addicts by administering smaller, but continuous doses The drug problem has assumed such large proportions that a physician has been placed in charge of the special narcotic control division of the New York police department This agency has cooperated with other forces throughout the United States and foreign countries until a clearing house has been established to supply information regarding drug addicts and venders The narcotic division has already collected the finger prints of 20 000 drug users in this country, Canada and Europe It has been stated that there are from 250 000 to 400,000 drug addicts in this country alone, and that the habit results in an annual loss of $750,000,000 Narcotics valued at $3 500,000 were confiscated and destroyed in New York alone during 1921, and 3,086 venders or users arrested

THE OTOLARYNGOLOGIST IN THE SCIFNCE AND ART OF MEDICINE AND SURGERY*

J A STUCKY, M D
LEXINGTON, KY

It can be truthfully said that this is the greatest year in the history of medicine and surgery, especially in the branch of otolaryngology and, as has been said by others, "it is conceded everywhere that the eye, ear, nose and throat specialists have attained the rank of a major branch of medicine and surgery When one compares the meager, almost barren specialty of twenty-five years ago in this subject, with the wonderful advances of the present day, one is amazed at the development a quarter of a century has brought forth Its scope and dimension have enormously enlarged and become a powerful and far reaching organization"

For years we have believed that the Mekka of medical learning and training was to be found principally in Europe or in the eastern part of our country, but the war has proved that in every department of life this, our own country, now leads the world No longer does a trip to Europe confer especial prestige or advantage, because today medical Europe is destined to sit at the feet of medical America The tremendous development of the past twenty-five years has been due to American initiative and skill, and in this period this specialty has advanced from a minor to a major branch of medicine and surgery, entitling American men to be the clinical teachers of the world The Vienna of ophthalmology and otolaryngology belongs not in Europe but in America Because the science and art of medicine and surgery and its special departments are not fixed but are in the process of development, the rapid progress being made by study and research becomes more fascinating and stimulating than ever before It is also equally true that no one of these specialties can exist without the other, or independently of them, but every specialist must do or have done some of the work of the internist "The aggressive research work and advanced improvements in operative technic have so changed the principles of otolaryngology that the methods of a quarter of a century ago have no place in our ranks today", then we lived in the adolescent stage of the science and art of medicine, and our diagnosis and treatment were largely based on symptoms and theory, but in the past decade we have passed from adolescence into the manhood of humanity and with it into the manhood of the science and art of medicine, and today we are governed not by theory but by facts The East now turns to the West, and where the North, South, West and Middle West formerly turned to the East for instruction and training, they now look not to one alone, but to one another A recent trip to the West and Middle West convinced me of the great work being done by those of whom we have heard only too little, and it can be truly said that the South, West and Middle West are coming into their own in the field of otolaryngology From a scientific standpoint it seems that we have nearly reached the summit of the diagnostic and surgical technic in our special field

Those who consult us either have symptoms indicating disturbed conditions of the ear, nose and throat due to a local determinable pathologic condition, or else these symptoms are but local manifestations of systemic conditions, and, since either or both may exist, it is expected and demanded of the otolaryngologist that he be able to decide the question

It is now recognized that the average case of diseased nares, pharynx or larynx must be relieved by changes brought about from within the body and not from those without The efficacy of the nebulizer, vaporizer, atomizer and topical applications of any kind is found in relatively few instances, and they are not indicated except as palliative measures

When the disturbed or diseased condition is not a local manifestation of a systemic condition, but is due to a local condition, it is a surgical condition and must be dealt with as such, with skill, precision and accuracy equal to that required in any part of the body, if the surrounding area is to be left with function unimpaired To differentiate between the systemic and surgical etiology and to prescribe the proper treatment, or resort to the safest and sanest surgical procedure, requires a diagnostic skill and surgical technic based on a thorough knowledge of more than the fundamental principles of medicine Besides a knowledge of anatomy, physiology, chemistry, biology and pathology, we must know materia medica and therapeutics in order to be able to recognize and successfully combat the disturbed metabolism The responsibility of the otolaryngologist is not only different from, but greater than that of any other special branch of medicine and surgery, in that we must preserve or restore both ventilation and drainage in order that these organs may function normally

It is no longer sufficient that the otolaryngologist be a skilful technician, able to see into or through the many ramifications in this special field, he must do so with little or no irritation or traumatism, he must be able to recognize the abnormal or pathologic and, in the majority of instances, to verify his conclusions by laboratory findings To do the best work with the best results, the otolaryngologist must not only be thoroughly trained, but his training must be founded on a knowledge of the branches mentioned, to which must be added at least some knowledge and experience of the internist, and, since this is too large a field for the average man to master, he must have the help and cooperation of the laboratory expert, the internist and the roentgenologist With all these he must be a thoughtful observer, thoroughly trained, a student of current medical literature pertaining to otolaryngology, and must attend scientific meetings such as these, in order to be able to interpret correctly what his eyes see and his fingers feel

Knowledge of the therapy of nutrition, food and pollen sensitization, and mastery of the mysterious field of endocrinology, I believe, will soon aid us in answering the challenge of immunization and anaphylaxis This brings us again to the question of medical education, which has occupied so much of the thought of the teachers of medicine in the last few years I am in accord with the views of Dr R B Canfield of Ann Arbor, Mich, that

> A consideration of the entire undergraduate medical curriculum is indicated and, in order to take it up intelligently the history of undergraduate medical teaching in the country for the past forty years must be reviewed At first it was entirely clinical, then the importance of laboratory teaching was recognized and stressed by energetic and progressive workers all over the country In order to devote more time

* Chairman's address read before the Section on Laryngology Otology and Rhinology at the Seventy Third Annual Session of the American Medical Association St Louis May, 1922

to preclinical work, the medical course was changed from two to three or four years, finally the premedical course was added and the combined course evolved, working toward two degrees At present the combined course of six years, leading to the degrees of bachelor of arts and science or doctor of medicine covers six or seven years and four or five years of this are devoted chiefly to preclinical work with the idea of securing a broader basis and education for studying clinical medicine While this seems too large a proportion of the time devoted to preclinical work, yet before any clinical course is cut down it would be wise to study critically exactly what is being taught throughout the undergraduate course, not only the names and courses with the hours devoted to them, but what is really in each course, and by comparison then with what is ideal, be better able to approximate the ideal Not enough hours are given to teach the student to see and recognize normal conditions of the ear drum, nasopharynx or larynx, let alone diagnose diseased conditions there, nor is there sufficient time to teach what every general practitioner should know The aim should be to graduate only doctors to care for the sick, without sacrificing anything essential in order to teach them preclinical work that is often forgotten before graduation, and could better be given to men in a postgraduate course, who wish to specialize in this line

The scope of otolaryngology has widened more in the last ten years than in any other branch of clinical medicine, and more time should be devoted to it The character of some of the preclinical work should be changed, courses should be cut down, and clinical work should be pushed farther back so as to give more time for clinical medicine and surgery

There seems to be an inclination to centralize authority in three departments, surgery, medicine and pathology, subordinating the so-called medical and surgical specialties of the three It would be a mistake to make heads of departments of clinical specialties, clinical professors, subordinate to full professors of surgery, and, if not overcome this tendency will lower the standard of teaching in the medical and surgical specialties and interfere with the progress in these departments Therefore a critical survey of the whole curriculum would be a good thing before any drastic change is made The chief function of the undergraduate school is to graduate young doctors, not specialists or expert technicians

The recent meeting of the Congress of American Physicians and Surgeons marks one of the most remarkable epochs in the history of medicine, in which otolaryngology occupied a conspicuous and important part Great progress was shown in the advancement made in the study of labyrinth function standardization test of hearing, and hitherto mooted questions in laryngology and rhinology were more satisfactorily answered Because of a nearer approach to scientific accuracy, the transactions of the three national societies which are a part of this congress (laryngologic, otologic and ophthalmologic) will contain a fund of information that none of us can afford to be without Two papers which were presented deserve especial mention, because of the startling facts brought out by two members of this section One of these was on "Some Unpleasand Local End-Results in Well Performed Tonsillectomies," by Dr C W Richardson of Washington, D C, and the other on "Fatalities of So-Called Minor Operations on the Nose and Throat Not Dependent on Anesthesia," by Dr H W Loeb of St Louis

What I have already briefly referred to should make us carefully consider the admonition of the president of the Congress of American Physicians and Surgeons, who says

The tendency to overspecialization in the practice of medicine has tempted many inadequately trained members of the profession to take up special lines of work There are too many specialists of this kind in practice today, and to correct this condition the members of this congress should promote and develop opportunities in various parts of the country for adequate postgraduate training in the several specialties of medicine and surgery

Dr Frank B Wynn, who has written "The Ten Commandments of Medical Ethics," says

Let it be granted that specialization, which has done so much for modern world progress, is likewise the chief glory of medicine, but we should not forget that as specialization in the commercial and industrial realm has led to narrow and selfish materialism, so is medical specialism in our day tending to forget man as an entity—a thinking, reacting aspiring being

Is it not meet at this time, therefore, that we seek a rejuvenation of medical ethics—not so much as a cold harsh rule of conduct, but as a revival of the finest things of professional life for which medicine in the past has always stood? In these days of arrant boastfulness by chiropractors, of preposterous claims by Christian scientists, with medical sects multiplying and breeding upon avarice, ignorance and erraticism should not the medical soul be aroused? Reviving the faith of our fathers, let us set the light of knowledge of the science and art of medicine and of medical ethics "upon a hill, that all the world may see and know the truth"

EFFECTS OF INTRATRACHEAL MEDICATION ON GAS BURNS OF THE RESPIRATORY TRACT*

LAFAYETTE PAGE, M D
INDIANAPOLIS

When we entered the war, the enemy was using mixed gases thrown over with shells from trench mortars and by heavy artillery The attacks usually began with gases which produced excessive sneezing and lacrimation, this being followed by the more poisonous gases mustard and phosgen Mustard gas, so called because its odor resembles that of mustard oil, classified as a vesicant causes inflammation, blistering, discoloration of skin acute conjunctivitis and intense inflammation of the respiratory passages Its action is caustic, the extent of damage or destruction of tissue depending on the degree of concentration and the time of exposure Its action may be delayed over a few hours to two or three days

Phosgen is classified as a lung irritant of suffocant type, which, in the alveoli and lung tissues, causes exudation of large quantities of frothy mucus, acute pulmonary edema and death, by flooding the air spaces

One of the most important and arduous duties of the throat and ear service throughout the war, after the introduction of poison gases, was the treatment of gas burns of the respiratory tract

The Allied Medical Service was completely overwhelmed for a time by the great number of casualties, and was without knowledge or means of proper treatment During my service in Base Hospital 32, located at Contrexeville, France, advance sector, from March 23, 1918 to the end of the war, 6,000 gas cases were received at our hospital for treatment Of this number

* Read before the Section on Laryngology, Otology and Rhinology at the Seventy Third Annual Session of the American Medical Association St Louis May 1922

2 800 were regarded as serious, requiring special treatment of the upper and lower respiratory tract Frequent examinations were made of these patients, both by direct and indirect laryngoscopy, and, when the condition of the patient permitted, bronchoscopic examinations were made A number of patients died in convoy from the front lines to the hospital Necropsies were made in these cases, and water color sketches representing conditions found in the respiratory tract and lungs were made by an assistant

Our first observations were made on a convoy of patients received, March 23, 1918 These patients were principally from Companies K and M, One Hundred and Sixty-Fifth Infantry, Forty-Second Division, and were gassed in the Lorraine Woods, American sector March 21 and 22, 1918 The following history was obtained

The gas attack was made with shells thrown from mortars and heavy artillery and was concentrated around the dugouts of Companies K and M, One Hundred and Sixty-Fifth Infantry When the attack began, all had on their gas masks and kept them on for two or three hours, when they were informed by their officers that it would be safe to remove them Many claimed that they felt a burning sensation in the lungs while they had on their masks, but, from reports made by others, it was evident that they removed their masks too soon and that the masks afforded perfect protection while they kept them on The first severe effects of the gas were felt in the eyes, at varying intervals of from one to three hours The respiratory effect developed from a few hours to several days after the attack A number of these patients had no symptoms of gas poisoning until they had slept under blankets which had been exposed to the gas

We had rarely witnessed such suffering and distress as these patients manifested, with skin burned and discolored, eyes swollen shut, spasms of choking vomiting and struggling for breath, with the lungs literally drowned by their own secretions, they writhed in pain until they became unconscious from the want of oxygen

Nausea, retching and vomiting, with pain and oppression over the chest, were among the earliest and most persistent symptoms, followed later by coughing and spasms of the glottis, with excessive discharge of frothy mucus often mixed with blood Hemorrhages from the nose and lungs were among the rare symptoms A deeply cyanosed and lead-colored face, labored respiration, rapid pulse, restlessness, constant and spasmodic efforts to expel the profuse frothy expectoration was the usual clinical picture during the first few days The pain and distress in the lungs and epigastric region was often very intense

PATHOLOGY

The pathology of gas burns is similar to that of an escharotic chemical applied to the tissues If gas sufficient to produce serious effects is inhaled, there results an extreme engorgement of all the vessels and capillaries of the lungs, followed by the outpouring of a serous exudate from the injured bronchial and alveolar linings In this stage, the patient might be drowned by the edematous exudate which filled the lungs, to the exclusion of the air As in other inflammations of a severe degree, the outpouring of the fluid exudate from the blood is followed by deposit of fibrin on the injured surfaces Thus, the bronchial passages, already wholly or partially denuded of epithelium, became lined or even occluded by a fibrinous membrane similar to that seen in diphtheria This greatly hindered respiration and adhered to the mucosa with such tenacity that coughing was ineffectual to dislodge it Necrosis of the bronchial walls and lung tissue resulted in a varying degree from exposure to the gas These areas were, of course, promptly invaded by whatever bacteria were present in the respiratory tract, resulting in ragged, foul ulceration of the larynx, trachea and bronchi, and in multiple abscesses of the lung

After the first few days, the burned areas became infected and began to suppurate As the necrotic process advanced, large quantities of exudate consisting of broken-down tissue, tube casts, greenish-gray masses of membrane and sometimes necrotic lung tissue, were thrown off from the air passages During this stage, the breath was very foul from the gangrenous discharges, and the patient, utterly exhausted from absorption of poison and the constant spasmodic and ineffectual effort to expel the accumulated slough, very often would lapse into a semiconscious state

EXAMINATION

In the milder forms of mustard-phosgen poisoning, we found the nasal laryngeal and bronchial mucosa red, dry or edematous, in the early stages The general appearance was not unlike an ordinary laryngitis or bronchitis After a short time, the membranes began to pour out large quantities of mucus In many of these cases of mild gassing, the patients recovered in a few days, and, in those patients who had been exposed to a high degree of gas concentration, the mucosa showed an intense hyperemia and dryness at first followed later by flooding of the air passages with the frothy mucus, often mixed with blood After two or three days, the burned areas were covered with a fibrinous membrane These patches were found in the vestibule of the nose, on the turbinates and, in some instances, extending into the accessory sinuses The mouth and pharynx seemed to show resistance to the caustic action of the gases, owing, probably, to the character of the epithelial lining, while the larynx, especially the arytenoid region, seemed to be particularly vulnerable Burns were often found to be deep with infiltration and edema about the vocal bands, causing aphonia, which occasionally persisted for weeks and months The tracheal lining was usually burned in irregular patches In many cases, the entire lining of the trachea extending into the small bronchi was involved Edema of the lungs was always present to a greater or less extent when there had been exposure to the mixture of mustard and phosgen in any high degree of concentration Bronchopneumonia with multiple abscesses was not infrequently present

TREATMENT

At this time (March 23, 1918), when we received our first convoy of patients at Base Hospital 32, the Allies had not developed any treatment which was satisfactory for the effects of poison gases in the respiratory tract and lungs Rest, bloodletting, oxygen inhalation and warmth were found to be of value in general treatment There was a large list of contraindications, such as, no form of opiate for pain, cough and spasm, digitalis for heart disturbance was contraindicated Epinephrin had not proved of value and was thought to be dangerous Oxygen seemed to be the chief remedial agent recommended by the Gas Service, but as there was not an oxygen tank in our hospital center during

the early months of our service, we found it necessary to resort to other forms of treatment Alkaline washes and sprays apparently increased the suppuration and aggravated the condition We felt at liberty to institute any form of treatment that promised relief, and as I had had several years experience in the treatment of laryngeal and bronchial affections with intratracheal medication, it seemed to be applicable in the conditions arising from gas intoxication The first object of the treatment was to relieve pain and the exhausting spasms and ineffectual cough without the use of opiates, and next, to obtain better drainage of the lungs and respiratory tract For these purposes it was found intratracheal medication was the most effective Medication in oil solution was introduced with the tracheal syringe during inspiration Skilled assistants soon learned the trick of introducing the syringe and administering the medicated oils in the trachea and bronchi In some patients who were peculiarly sensitive to any kind of throat medication, it was at first necessary to spray the pharynx with a 2 to 4 per cent solution of cocain before introducing the syringe

The principal medicines used were solutions or emulsions in liquid petrolatum or olive oil, of either bismuth, iodoform, antipyrin, guaiacol or camphor menthol The following formula was found to be the most generally effective in the majority of cases Guaiacol, camphor menthol, 5 per cent of each in liquid petrolatum or olive oil From 1 to 3 drams of this mixture was introduced into the trachea two or three times a day in the severe cases

MODE OF ACTION

When the oil solution reached the deeper bronchi a few seconds after introduction the first effect produced was a cough, which expelled the contents of the bronchial tubes, often consisting of tube casts and diphtheritic membrane, grayish green, with pus, and other products of suppuration which had accumulated in the trachea, and which previous efforts of coughing had not been sufficient to expel The natural drainage of the lungs was facilitated by the action of the camphor menthol on the inflamed, swollen mucosa, while the guaiacol acted as an antiseptic and anesthetic The necrotic membranous exudate became more easily detached under the action of the liquid petrolatum, and easier breathing and better oxygenation were at once noticeable, as well as a diminution of the coughs and spasms Relief of pain, with a sense of comfort throughout the lungs, usually followed with rest and better oxygenation, the general toxic condition of the patient improved

Without exception, these patients expressed themselves as receiving great relief, and, when suffering, requested the treatment Those who received the treatment usually made a quick recovery, and most of them were able to return to the lines in a surprisingly short time, considering their condition when they entered the hospital

Of the 6,000 gas patients who passed through our hospital, only two died These deaths occurred within the first twenty-four hours after admittance

The results were so encouraging at Base Hospital 32 that the treatment was recommended in the official bulletin of the Allied Gas Service, in April, 1918

CONCLUSIONS

1 Intratracheal medication is clearly indicated in all forms of inflammation of the lower respiratory tract resulting from the caustic action of poison gases It should be used as early as possible after gassing, for the purpose of relieving the first symptoms of pain and asphyxia and reducing the extent of secondary infection, by facilitating drainage of the trachea and bronchi and rendering the passages as sterile as possible, through the antiseptic properties of the oil solutions

2 This method of treatment shortens the process of suppuration in the secondary stage by aiding the lung reflexes in expelling the necrotic membranes and products of inflammation, and in healing the ulcerated surfaces, thus relieving the strain on the nerve centers and checking the cough and spasmodic efforts to expel the debris and thus improving oxidation, diminishing toxic absorption and affording rest to the whole organism

3 Through shortening the healing process, the permanent damage to the pulmonary mechanism is lessened, there is less surface denuded of epithelium, less scar formation, less peribronchial thickening and, consequently less tendency to chronic bronchitis and predisposition to tuberculous infection

4 We are convinced from our observations and experience in using this treatment, before, during and since the war, that all forms of laryngitis, bronchitis, bronchiectasis and asthma, with all the different kinds of distressing coughs and spasms associated with these affections, are more quickly and effectually relieved by this form of treatment, and its use is urged in this class of disorders

Hume Mansur Building

ABSTRACT OF DISCUSSION

DR NORVAL H PIERCE Chicago I was chief of the surgical service at Vichy during the war and our hospital was supposed to be a head hospital so we should have seen a great many of these gas cases However, the exigencies of war compel me to say that as far as my overseas service is concerned I can tell you more about compound comminuted fractures than about gas burns of the upper respiratory tract In fact we saw very few severe burns of the respiratory tract We saw many more burns of the scrotum and of the lower extremities I believe Dr Page is right in recommending petroleum oil as an aid in the treatment of these cases of burns of the respiratory tract I do not think it makes much difference what you put in that oil It is largely the petroleum oil itself that does the work. Liquid petroleum has a remarkable influence in dissolving these fibrinous exudates I believe however, that an ingredient that would add to the efficiency of the liquid petroleum is oil of peppermint It has been pretty well proved that mucous discharge is saponified is largely made up of bubbles of air and that oil of peppermint will overcome the surface pressure of these minute globules of air Large collections of mucopus in the nose dissolve into almost nothing when liquid petroleum containing this oil is introduced I do not believe that the other ethereal oils have the same effect

DR BURT R SHURLY Detroit I was a neighbor of Dr Page in France just half a mile away, and we received an equal number of these gas cases It seems to me that this method of treatment should have a definite standardized basis for its usefulness Having used it for some years as an ordinary routine procedure I believe absolutely in its value in certain cases I used 2 5 per cent guaiacol and 2 per cent camphor-menthol in olive oil by intratracheal injection in a number of cases with decided palliative and beneficial effect I think this method should have a definite standardized use to be used in the same way as we would use sterile castor oil in the eye in case of burns At least it would be a palliative measure and give relief

DR WENDELL C PHILLIPS, New York This discussion should not close without emphasis being laid on the importance of this type of treatment in civilian practice I recall the first paper read on this subject before our American societies by Dr Thompson of Cincinnati, in which he emphasized the benefits that might be received in laryngeal and tracheal inflammation from intratracheal injections of remedial agents, with a base of sterile sweet oil I use 1 per cent menthol and 1 per cent guaiacol, emphasizing an intratracheal syringe Train patients to take this remedy and it is marvelous what relief they obtain in those peculiar and distressing inflammatory processes involving the larynx trachea and upper bronchial tubes I do not know how the inflammations of the grip type have affected patients in other parts of the country, but during the past winter in New York we have been confronted with patients suffering from a most distressing and persistent tracheal inflammatory process in which cough was the chief symptom This cough was so distressing that the patients became more or less exhausted, with a daily slight rise of temperature It was almost impossible to get relief from any form of treatment except intratracheal injections In my own practice, it is the standard, daily method of treating this type of case We had some trouble getting satisfactory syringes I have seen several varieties, but the one I get from Tieman & Company, New York, is the best It has a very short barrel and a sharp curve

DR LAFAYETTE PAGE Indianapolis Dr Pierce has emphasized the value of the oils in intratracheal medication as well as their use in the upper respiratory tract for dissolving and loosening inflammatory products In my experience camphor-menthol, as an addition to the oils, has proved of undoubted value in the treatment of nose and throat affections, and with the addition of guaiacol bronchial affections yield much more readily I am glad that Dr Phillips has given his experience with intratracheal treatment in the laryngeal and bronchial affections associated with the recent epidemic of influenza It is encouraging to know that such an experienced observer also shares my enthusiasm in the use of this form of treatment In the early stages of influenza, before the disease has invaded the lower respiratory tract, it has decided value as a prophylactic measure, later on, the distressing cough and irritation of larynx and trachea are more quickly and effectively relieved by this treatment than by any other known to me

A STUDY OF HYPOTENSION*

STEWART R ROBERTS, M D
ATLANTA, GA

Hypotension is one of the indefinite problems of medicine Few articles have been written on the subject, compared to the large number on hypertension The studies thus far have been far more pharmacologic, experimental and surgical than clinical, and directly related to internal medicine This is shown by the researches of Crile,[1] Cannon[2] and Rich,[3] as compared with the paucity of researches by internists Huchard and Mougeot,[4] Grasset and Calmette,[5] Muenzer,[6] Knapp[7] Martinet[8] and Reynaud,[9] in Europe, and Piersol,[10] Emerson,[11] Lawrence,[12] McCrae[13] and Goodman,[14] in America, have discussed the subject from various points of view Faught[15] says that "unfortunately the literature almost entirely lacks exhaustive studies of low blood systolic pressures," and Goepp[16] says that "a little attention has been given to the subject, at least in its relation to chronic disease" Sir Clifford Allbutt[17] probably expressed the general feeling of internists when he wrote of hypotension that it is "a study that I have yet to begin" The research problems afforded by the subject are numerous and inviting

Each writer has arbitrarily stated his opinion of the lowest limit of normal systolic pressure and at what figure hypotension really begins There is no general agreement among internists as to the upper systolic limit of hypotension Janeway[18] placed the upper limit at 100 mm, and Oliver[19] at 125 mm The limit is stated in terms of palpatory readings by some authors, and in terms of auscultatory readings by others Each series of hypotension pressures tends to vary according to the opinion of the writer as to what constitutes hypotension, and this in turn varies according as the pulse readings are by palpation or by auscultation

The majority of authors place hypotension at 110 mm and below Very little is said about the diastolic pressure Out of our second series with 350 cases, 118 had a systolic reading of 110 mm, or more than 33 per cent In this study, 110 mm and below, systolic pressure, is assumed to constitute hypotension All readings were by the stethoscope and auscultation, were taken three times at a single examination, the patients were lying on their backs, and a mercury instrument was used As a rule, the patients were ambulatory office patients in private practice, except as otherwise indicated in Table 10

CLASSIFICATION OF HYPOTENSION

One obstacle to a better understanding of low blood pressure has been the absence of any general classification other than to state that certain individuals in apparent health had low pressure, and that certain diseases were characterized by the condition The internist gives Addison's disease and tuberculosis as examples of disease with hypotension, and the surgeon accents shock With our present knowledge, a classification is based only on the conditions in which hypotension occurs, and cannot be a causal classification

The association of hypotension with a disease does not mean that the associated disease is the cause of the hypotension It may be or it may not be Association is not necessarily cause An individual with hypotension, whether in health or with any medical or surgical condition may be placed in a general class, according to the classification given below With this as a starting point further exact studies on the causes of low tension become possible

TABLE 1—GENERAL PRESSURE AVERAGES AND TOTALS

	Number Cases	Heart Normal	Heart Diseased	Systolic Pressure	Diastolic Pressure	Pulse Pressure	Pulse
Hyperpressure	131	57	74	176	103	73	85
Normal pressure	164	123	39	130	79	51	83

Totals	500	345	155				

of the infections, surgical conditions, and nutrition in general A heart suddenly thrown into auricular fibrillation may be the variable factor in one case The pump has gone wrong The vessels may be the variable factor in a faint The bed has gone wrong In such a case the nervous system is the outside influence on the vessel An advanced anemia with cachexia or a severe hemorrhage may be the variable factor in another case The stream has gone wrong But probably more perplexing from the point of view of pure physiology are those healthy persons, or apparently healthy persons with low tension Where does the cause lie in these?

Five series of cases are presented for study and analysis Series 1 includes 205 cases of hypotension collected in 1917

As indicated by Table 1 of the 500 cases 131, or 26 per cent were hypertension cases, 164, or 33 per cent normal and 205, or 41 per cent, hypotension cases After all that has been done on hypertension, it is

1 Hypotension associated with comparative health

2 Hypotension associated with complaints of weakness inertia and easy exhaustion Somasthenia Somasthenic states Somasthenics

3 Hypotension associated with disease as cardiac disease tuberculosis anemia fevers and infections

4 Hypotension in surgery as in trauma hemorrhage anesthesia or shock

5 Hypotension in experiment, as with drugs after suprarenalectomy, and experimental surgical states

With the foregoing simple divisions in mind, hypotension becomes a problem of physiology primarily and of pathology secondarily It is a problem of the circulation The circulation is a closed system consisting of the heart, the vessels—artery capillary and vein—and the blood The pump the bed and the stream are the three factors They are variables in the constant that we call the circulation The cause of hypotension lies somewhere among these three factors It may involve one, two or all three of them Two of them, the heart and the vessel are under the varying influences of the nervous system, the endocrines and the metabolism, and all three are under the influence

somewhat surprising to find a larger percentage of the hypotension cases One notes that the higher the pressure the larger the percentage of diseased hearts 56 per cent in the hypertension as against 20 per cent in the hypotension cases Further there were more diseased hearts in the normal pressures than in the low pressures 24 per cent as against 20 per cent

Between the systolic hypertension and hypotension, there is a difference of 67 mm , between the diastolic pressures a difference of 33 mm , and between the pulse pressures a difference of 34 mm The swing upward the plus amplitude above normal, is greater than the swing downward below normal, the minus amplitude In the hypotension cases there is a less proportionate fall in the diastolic pressures than in the systolic and pulse pressures The circulatory mechanism tends to conserve the diastolic pressure, in hypertension it does not usually rise proportionately to the systolic pressure and in hypotension cases it tends to cling closer to the normal

The variations in the pulse rate were slight The hypertension cases show 85 against 81 in hypotension

Perhaps a factor here is, as has been already noted, the higher the pressure the worse the heart in the series, the lower the pressure, the more normal the heart and the lower the pulse Lower pressures tend slightly to lower pulse rates

TABLE 4—PRESSURE BY DISEASES

Diagnosis	No	Age	Sex M	Sex F	Heart Normal	Heart Diseased	Systolic Pressure	Diastolic Pressure	Pulse Pressure	Pulse
Digestive system	21	42	10	11	21		110	69	41	81

Pelvic disease	4	44		4	4		111	77	34	76

Table 2 shows hypotension rather equally distributed between the sexes, 103 males and 102 females The average age for hypertension is about 9 years above that for hypotension The hypertension cases show an average higher pressure in women of 7 mm whereas, in the hypotension cases the two sexes show practically the same pressures The diastolic pressures are lower in women The pulse pressures vary only 1 mm The pulse rate with hypotension in women is 5 higher than in men

Table 3 is an analysis of the 205 hypotension cases by diseases, decades and sex There is little noticeable difference in the sexes, except that the neuroses and pellagra are more prevalent in women, and tuberculosis intoxications and infections in men Disease rather than hypotension is the determining factor The second, third and fourth decades are, as a rule, the decades of hypotension, though the relative hypotension in the decrescent sclerosis of the aged is a notable exception Under somasthenia, to be discussed later, is a group of thirteen men and eleven women, with no mental or nervous symptoms, that I have called somasthenics

TABLE 5—ABSOLUTE AND RELATIVE HYPOPRESSURE

Diagnosis	No	Age	Sex M	Sex F	Heart Normal	Heart Diseased	Systolic Pressure	Diastolic Pressure	Pulse Pressure	Pulse
Absolute hypopressure	89	36	42	47	75	14	100	69	31	81
Relative hypopressure	116	45	61	55	90	26	116	72	44	80

Table 4 gives hypotension by disease, group, number, average, sex, and relation to the condition of the heart The lowest average is in the anemias, and the highest in the circulatory diseases, advanced age in the last group is a probable factor, and the term "relative hypotension" is used for cases below the normal for the age of the individual The somasthenics average only 107 mm The average age in tuberculosis is 36, and the pressure only 105 mm With the exception of four groups, the pulse pressures average in each group from 34 to 39 mm The pulse is notably uniform

Table 5 refers to comparison of absolute hypotension, i e, cases with a systolic pressure of 110 mm or below and cases of what in this first series of 205 cases is called relative hypotension, to be discussed later Two facts are evident from this table (*a*) The lower the pressure, the less frequent are pathologic conditions of the heart (*b*) The rate of the pulse is not a determining factor in hypotension with a difference of 16 mm in the systolic pressures In the two cases, the pulse rate shows a variation of only 1

Table 6 gives the complaints in order of frequency These are the personal complaints of the patients and the reasons that caused them to seek medical aid Of the 205 patients, sixty-two, or 30 per cent complained of exhaustion, thirty-one, or 15 per cent, of nervousness, twenty-eight, or 14 per cent, of headache, twenty-one, or 10 per cent of indigestion, sixteen, or 8 per cent, of constipation, the same number of abdominal pain, fourteen, or 7 per cent, of pain or numbness in the extremities, and twelve, or 6 per cent, of backache or phobias The chief symptoms in order are exhaustion, nervousness and headache I did not find as large a percentage of vertigos as did Goodman[14] —only eight cases in the series

Table 7 represents 3,389 persons with hypotension accepted for insurance by the Northwestern Insurance

TABLE 6—COMPLAINTS IN ORDER OF FREQUENCY

Exhaustion	62	Vertigo	8

Company to Oct 1, 1920 The pressure in these cases ranged from 90 to 100 mm by palpation This would average from 100 to 110 mm by auscultation This includes a period of eight years from 1913 to 1920, inclusive There were only twenty-six deaths, and of these eight were casualties and ten were due to influenzal pneumonia, with only eight due to other diseases The medical director[20] states that

> The company has declined comparatively few cases wholly on account of low arterial tension In those cases declined with a low blood pressure there were other impairments which led to the rejection of the applicant We have not found in any of our death claims of insured members, where, for instance, the death was due to tuberculosis within two years of the issuance of the policy of insurance, that the

20 Fisher J W Personal communication to the author

blood pressure at the time of the approval of the application varied perceptibly from the averages for the age

Table 8 represents an analysis by age, pressure and hemoglobin of 350 cases of hypotension occurring in 1,950 cases in private practice, or approximately 18 per cent The women outnumber the men by thirty

TABLE 8—ANALYSIS BY AGE BLOOD PRESSURE AND HEMOGLOBIN OF THREE HUNDRED AND FIFTY CASES OF HYPOTENSION

	Average Age	Blood Pressure			Hemoglobin by Sex
		Systolic	Diastolic	Pulse	
Men (160)	38	107	67	40	79
Women (190)	34	104	68	36	83

or approximately 19 per cent This would seem to indicate that hypotension is more common in women than in men, as the two sexes occur in nearly equal numbers in the series of these 1,950 patients, 974 were men and 976 were women It is significant that the blood pressure among the women is 2 mm higher, though their average age is four years less than the men Further, the hemoglobin is 4 degrees higher than the men, 83 compared to 79 We have felt that this discrepancy in the hemoglobin is probably due to the fact that men as a rule wait longer to consult a physician and allow their pathologic condition to advance further than women They are sicker when they come for diagnosis than women Further, in the Southern states, an average of 83 per cent hemoglobin by the Dare hemoglobinometer is certainly a fair average for women, much less diseased women

TABLE 9—DISEASES IN THREE HUNDRED AND FIFTY CASES OF HYPOTENSION (MEN 160 WOMEN 190) CLASSIFIED BY SYSTEMS

Digestive system	190	Psychoneuroses	58
Vascular system	134	Psychoses	3
Arteriosclerosis	4	Diseases of metabolism	12
Secondary anemia	56	Tuberculosis	20
Angina pectoris	1	Chronic tonsillitis	102
Mitral disease	15	Pyorrhea	43
Hypertrophy of heart	10	Periapical infection	34
Myocardial insufficiency	15	Miscellaneous infection	37
Miscellaneous	98	Intoxications	17
Pelvic diseases	55	Pellagra	22
Urinary diseases	7	Somasthenia	3
Respiratory disease	35	Endocrine system	6
Diseases of nervous system	19	Miscellaneous	24

Table 9 is an analysis of the diagnosis of these 350 cases of hypotension arranged by systems of organs There is some interesting evidence in this analysis One patient may have several diseases present Each patient, as a rule, has more than one disease or one condition present There were 1,002 different diseases in the 350 patients, or an average of nearly three per patient The diseases of the digestive system lead with 190, next, the vascular system with 134 It is interesting to note that there are fifty-six cases of secondary anemia This and tonsillitis are very frequent chronic diseases in the Southern states [21] An anemia not primary, which by the Dare hemoglobinometer is 70 or below, is classified in this series as secondary anemia There are only four cases of arteriosclerosis in 350 cases of hypotension, and all the cases of cardiac hypertrophy and myocardial insufficiency were associated with mitral disease Unless some other disease is present, we have uniformly found mitral stenosis to be associated with hypotension Pelvic diseases number fifty-five, of which laceration of the perineum is more frequent with its accompanying rectocele and cystocele, next, laceration of the cervix with accompanying cervicitis, and lastly, fibroid tumors are the three most frequent conditions in this group Most interesting of all probably is the large number of cases of chronic tonsillitis, 102, pyorrhea, 43, and periapical infection, 34 It is our impression that chronic focal infections tend to secondary anemia and hypotension Of course, the exceptions to this impression are most numerous There are twenty-five cases of somasthenia or one case of every fourteen of hypotension

Table 10 includes 101 negroes, of whom forty-seven were men and fifty-four women of 20 years and older Women outnumber men by seven, and their average age is 7 years less The systolic pressure in men is only 1 mm more than in women The diastolic pressure is the same in the two sexes, and the pulse pressure in women 1 mm less It seems that the two sexes when sick give the same hypotension averages though the men average 7 years older These negroes were sick in the general medical wards, and included chiefly infectious diseases, such as typhoid and pneumonia heart disease diabetes, diarrheas, malignancies, syphilis and arthritis These 101 cases of hypotension occurred in 289 adult negroes, of whom 167 were men and 122 were women Of the total, 35 per cent had hypotension I have no figures showing the blood pressure averages in normal adult negroes, but it is my impression that blood pressure in normal negroes is somewhat lower than it is in normal white persons in the Southern states, though we have no actual figures to compare or to prove this statement It is simply a clinical impression

TABLE 10—FINDINGS IN TWO HUNDRED AND EIGHTY ONE ADULT NEGROES

Blood Pressure	Male	Age	Systolic	Diastolic	Pulse	Female	Age	Systolic	Diastolic	Pulse	Total No
Low	4	39	103	67	35	54	25	102	68	34	101
Normal	39	39	127	79	48	34	33	124	84	40	123
High	4	42	191	124	67	2	48	182	116	66	5

Table 11 includes twenty-nine white adults, of whom sixteen were men and thirteen women The average age of the men is fifty-eight and of the women fifty-three The average systolic pressures are the same There is a variation of 8 less in the diastolic pressure in women and 8 more in the pulse pressure in women The hemoglobin in both sexes is above 70 and would not be considered low in the South for this average age From a study of this table and all the cases that compose it, we are impressed with the fact that the hemoglobin is not a determining factor in hypotension To express it differently, a person may have a hemoglobin of 90 and a hypertension lower than

TABLE 11—RELATIVE HYPOTENSION BLOOD PRESSURE 111 TO 114 INCLUSIVE IN PERSONS AGED 45 YEARS AND OVER

	Number	Age	Systolic Pressure	Diastolic Pressure	Pulse Pressure	Hemoglobin
Male	16	58	112	79	33	73 Highest 90 Lowest 50
Female	13	53	112	71	41	71 Highest 85 Lowest 50

another person of approximately the same age with a hemoglobin of 50

RELATIVE HYPOTENSION

The mooted clinical phrase "relative hypotension" seems to have been used with three different meanings

(*a*) The phrase seems to have been applied to a loosely used clinical rule that the average blood pressure for a person of 20 years of age is 120, and that normally the pressure should increase 1 mm of mercury for every two years of age over 20 If, for example, a person under this rule is 60 years of age, he should have a blood pressure of 140 mm If, now, his pressure is 125, it is 15 mm below the normal for the age of 60, and under this use of the term he is said to have a relative hypotension

(*b*) A second clinical use of this phrase has been made in reference to hypertension cases which, as a result of treatment or advancing disease, show a decided drop from their former hypertension level As a result of this drop they are said to be in a state of "relative hypotension," even though the blood pressure may be above normal For example, a person with chronic nephritis and a blood pressure of 220 mm may, as a result of cardiac dilatation and myocardial decompensation, develop a rather rapid fall in blood pressure to 150 mm Under this use of the term he has a "relative hypotension"

(*c*) It is clearly evident that either of these two applications of relative hypotension is rather unnecessary The first is an arbitrary application of an arbitrary rule that sharply relates blood pressure in millimeters of mercury to age in years This does not permit accurate conclusions The second use is unnecessary because it simply expresses a fall in blood pressure from hypertension to less hypertension or to normal

There is, however, a class of cases that we have come to feel justify the application of the term "relative hypotension" Out of our last series of 1,950 private cases there are twenty-nine cases listed in Table 11 which are far below the normal for these individuals The clinical impression prevails that a person of 45 years or older ought to have a systolic pressure of 120 mm If his pressure is between 110 mm, or the beginning of hypotension, and 120 mm, the average of normal tension, the case belongs in the relatively infrequent class to which with reason we may apply the term 'relative hypotension" We would therefore restrict it to persons of 45 years and older whose pressure ranges from 111 to 119 mm, both inclusive

SOMASTHENIA

In the first series of 205 cases are included twenty-four cases and, in our last series of 350 cases, twenty-five cases, or a total of forty-nine patients whose condition seems to partake of chronic exhaustion or of inability to maintain a normal active life without easy exhaustion, and the chief demonstrable condition seems to be hypotension Goodman [14] called attention to what he termed "cases of low blood pressure occurring in the absence of any demonstrable organic lesion These have been patients, for the greater part, on the ascent of the crest of the curve of life" He gives five illustrative cases, with variable symptoms, foremost among them being vertigo, and mental and physical fatigue They were improved by exercise, elimination and large doses of nux vomica In different words, Lawrence [12] calls attention to the same syndrome He includes such symtoms as "apathy, sometimes amounting to actual physical weakness, poor appetite and sleep, and tendency to headache after ordinary exertion" In short, the patients are unable to perform what is an easy day's work for the normal individual without experiencing symptoms of fatigue The condition is usually diagnosed as neurasthenia, debility or, in the absence of an examination of the blood, anemia

The group may be thus characterized

1 Age between 20 and 40 years, rarely after 40
2 Women predominate
3 Complaints, in order of frequency, are exhaustion, nervousness, headache, pains in chest, abdomen or extremities, indigestion, constipation, backache, dyspnea, insomnia and palpitation

The three chief complaints are exhaustion, lack of endurance and headache Low blood pressure is present The patients are not neurasthenics, and, apart from the diagnosis of visceroptosis or mild focal infections or hypochlorhydria or secondary anemia, no actual pathologic condition can be demonstrated These cases cannot be classified under the psychoneuroses The term somasthenia is applied to the condition, and the term somasthenic to the patient

CONCLUSIONS

A consideration of the blood pressure records of 440 cases of absolute hypotension and 145 cases of relative hypotension suggests that

1 Hypotension seems generally to be equally distributed between the sexes

2 Hypotension patients have proportionately more normal hearts than have normal persons or hypertension patients As the pressure rises the heart is more likely to be diseased

3 The pulse rate is not a determining factor in hypotension It tends to rise only very slightly with rising pressure

4 The rate of the pulse is more dependent on the sex than on the blood pressure, as indicated by Table 2

5 Hypotension may accompany different diseases It is difficult to prove the influence of the disease in the causation of the hypotension because, as a rule, the pressure before disease is unknown

6 The lowest pressures occur in secondary anemia, pellagra, somasthenia, neuroses, tuberculosis and the acute infections of the respiratory tract

7 Relative hypotension is a term that should probably be restricted to persons of 45 years and older whose pressure ranges between 111 and 119, both inclusive

8 The classification of hypotension is important because it separates hypotension in health from hypotension in disease and makes clearer the intricate problems of low blood pressure

9 Hypotension is not a bar to insurance in the old line companies, although in one series of 3,389 accepted candidates, the death rate was two thirds greater than the expectancy tables would indicate

10 Women seem to develop hypotension at an earlier age than men, as indicated by two series of cases

11 The percentage of the hemoglobin is not a determining factor in hypotension

12 In diseases of the circulation, secondary anemia is the most common accompaniment of hypotension Arteriosclerosis and myocardial diseases are relatively rare

13 Focal infections are common accompaniments of hypotension

14 In sick adult negroes there are more cases of absolute hypotension than of hypertension

15 Hypotension seems to tend to accompany acute diseases characterized by fever and chronic diseases characterized by diarrheas, as amebic dysentery, sprue and pellagra

---

ABSTRACT OF DISCUSSION

DR GEORGE DOCK, St Louis It is interesting to see that in most of Dr Roberts' cases with hypotension the diastolic pressure does not seem to be very low I have noticed that in my own cases A patient may have a low pressure systolically, but a diastolic pressure of 80 or 85 This must play an important part in the symptoms of some cases, and a more careful study of the diastolic and systolic pressures might show some interesting features Most patients have appeared because their pressure was high and they have an exaggerated fear of high pressure They have an idea that there are certain norms, and then if a man of 50 has a pressure of 150 he gets alarmed over it I venture to say that the knowledge of this paper will spread People will learn that there are low pressures, they will have their pressures taken, find they are low, and we shall have a better opportunity to study cases than we have had heretofore with only accidental material Some of these cases are the result of incidental disease, such as pneumonia Others seem to be associated with defective conditions muscular and otherwise which are extremely important and sometimes extremely annoying to the patient

DR JOHN PHILLIPS, Cleveland Dr Roberts' paper is particularly timely because of the tendency until very recently to pay little if any, attention to hypotension probably because of the especial menace of hypertension—the development of arteriosclerosis It is especially important that we should not diagnose the presence of either hypotension or hypertension on the evidence of a single estimation of the blood pressure although there is more chance of error in the case of hypertension, since the blood pressure tends to rise under excitement Sometimes a blood pressure measurement on a patient's first visit to the physician may be from 50 to 60 mm higher than on the second visit These cases fall into several groups clinically One group as Dr Roberts said, comprises persons in apparent health Another group consists of persons who are easily exhausted these for the most part being women who lead an active social life Many of them have visceroptosis, and on inquiring into their childhood history, one finds that they were inclined to faint in school and showed orthostatic albuminuria In another group the hypotension follows an infection influenza in particular These cases show a persistently low systolic blood pressure Rolleston has asserted that the hypotension in these cases is due to some disturbance of the suprarenals by the toxin of influenza Another group includes the myocardial cases in which, as Dr Dock has said, the systolic pressure may be low but the diastolic pressure will be elevated so that the pulse pressure will be only 20 Such a condition is pretty good evidence that there is a weakened myocardium Still another group comprises the anemias with the exception of certain types of anemia which are associated with marked lowering of the kidney function with high blood urea and a low phenolsulphonephthalein output In these cases hypertension rather than hypotension is present In pernicious anemia the blood pressure is low, as a rule

DR. JOHN G MCLAURIN, Dallas, Texas Just what is to be considered hypotension? It has never been well defined In fact, it varies greatly so that what is considered hypotension in one person might not be considered such in another person of the same age It is probable that a systolic pressure below 110 in a person of 35 should be considered as hypotension To state just what constitutes a diastolic hypotension is still more difficult High blood pressure has been diligently studied for a long time, but low blood pressure, which is almost as important a symptom, has been sadly neglected Hypotension is dependent on some pathologic condition, and it is important that this should be looked for, a careful search will usually reveal the true condition responsible for it Sometimes the etiologic factor is quite evident It is usually present in acute infection such as typhoid fever pneumonia and influenza And, I think, it is fortunate that the blood pressure has been low in these acute infections The hemorrhage in typhoid fever is probably to some extent controlled by hypotension Then it is seen in certain chronic infections such as tuberculosis, in myocardial degeneration from lack of muscle tone, in a decompensating heart, and in anemia of the heart muscle Sometimes it occurs at the height of an attack of angina pectoris Internal glandular disturbances, such as diseases that diminish the secretion of the suprarenals are associated with hypotension It may occur in hypothyroidism and hypopituitarism, in the menopause, probably being a disturbance in the endocrine system Focal infections may also play their part, whether it is the effect of a liberated toxin on the musculature of the arterioles or a toxin action on the nerve control of the arteriole, is not definitely known I am of the opinion that it is usually an arteriole dilatation resulting from a partial paralysis of the vasoconstrictors due to a toxin I do not believe in the existence of essential hypotension It is a symptom, not a disease Hypotension is frequently the cause of considerable discomfort and probably in many cases more discomfort than would result from the same degree of hypotension

DR L F BISHOP, New York I can hardly agree with Dr Roberts that this subject has not been written about The literature is quite extensive and, strangely enough, the Italian literature has been particularly rich in it The consideration of the low blood pressure patient has been before us for a long time in different forms We can divide cases into three important groups first, the hypotension that is due to auto intoxication or infection of some kind In many instances this group constitutes the early stage of high blood pressure The persons who in early life suffer from low blood pressure of an infectious type will later on have high blood pressure The second group is the group which I classified twenty years ago as constitutional low arterial tension This is simply naming in another way a condition for which every clinician has a name I think that Dr McKenzie called it the X disease The army men included it in neurocirculatory asthenia It is a constitutional condition These persons have a defective circulatory mechanism which manifests itself in low blood pressure These people are the so-called neurasthenics and we have to recognize them as a definite group They do better on forced outdoor exercise and a good hygienic regimen They live to a miserable old age and they all suffer from some circulatory defect Probably endocrinology will give us a clue to this problem Then there is the group of secondary low blood pressure cases The measurement is not low but it is low compared to what the patient has been carrying The patient may come into the hospital with a systolic blood pressure of 180 but still it may be a relatively low blood pressure as it is below the pressure of 200 which he has been carrying The main point is that we must not allow primary low blood pressure to cause anxiety to ourselves or to our patients My experience is that in all of these cases, when disease or accident demands a higher pressure nature will produce it The final point I want to make is that low blood pressure has very little to do with heart disease and is a matter of the nervous system and peripheral blood vessels

DR ALEXANDER LAMBERT New York No doubt many disease conditions produce low blood pressure and many healthy persons carry low blood pressure and show no symptoms They are vigorous people I remember a patient who had a systolic pressure of 69 Then it rose to 160 Then he had an attack of tobacco angina and his pressure dropped back to 89 Later it had risen to 120 Low blood pressure is consistent with good health and not necessarily a disease condition That is my one point

DR LOYD THOMPSON, Hot Springs, Ark I have noted a rather persistently low blood pressure in late syphilis, that is, syphilis after one year About 90 per cent of these cases show a blood pressure of below 90 or below 110 at the highest

DR ELLSWORTH SMITH, St Louis It has been said that hypotension is not associated with arteriosclerosis While it may not be associated with arteriosclerosis, of course, nearly as often as is hypertension, still there is a well defined group of cases of arteriosclerosis with hypotension, the case in which the sclerosis is developing as a primary degenerative process in the arterial walls not secondary to hypertension In the hypertension cases, the cause of the sclerosis is the strain on the vessel wall, but in these so-called involutionary forms of arteriosclerosis, well defined arteriosclerosis even to the pipe stem beaded vessels may be present with a very low blood pressure I want also to accentuate the fact brought out by Dr Dock, and that is the importance of the diastolic pressure in these cases I agree with him that this explains very largely those cases of persons who go through life comfortably with their circulation perfectly compensated although the systolic pressure is quite low

DR STEWART R ROBERTS, Atlanta I am disposed to agree with most of the speakers in what they have said The anesthetists find that with a falling diastolic pressure during anesthesia they can foretell the beginning of danger and the onset of shock for twenty minutes before serious symptoms arise The surgeons on the western front during the war gave a rather unfavorable prognosis in those cases in which there was a diastolic pressure of 60 when the patients came into the casualty stations Each of us in internal medicine sees ambulatory cases in which the diastolic pressure is 60 or below It is impossible within the time allowed to go into the various phases of this subject For instance, on the Gulf Coast more persons have hypotension than hypertension Dr Thayer referred to this phase of the subject many years ago We have one patient whose pressure is reduced 25 mm by a hot bath Newberger has written on the influence of heat in producing hypotension Such phases of the question will be discussed in the future

---

AN ANALYSIS OF A SERIES OF CASE RECORDS RELATIVE TO CERTAIN PHASES OF BREAST FEEDING*

HENRY DIETRICH, M D
LOS ANGELES

This analytic study is based on a series of 1,000 records of almost consecutive cases seen in private practice Hospital and welfare records are purposely omitted because I wish to demonstrate what happens to the infant of the middle class of our population

These patients employed a physician to care for mother and child during and, frequently, also after the obstetric period Most mothers and nurslings are, and should be, cared for by the general practitioner If we approach the subject from this practical standpoint, the general practitioner, whom I shall speak of as the obstetrician, must be impressed with the fact that he is constantly responsible for two patients, the mother and the child Once imbued with this fact, he should aim to become as proficient in the care of the nursling, in all phases of its welfare, as he is in the care of the mother

The obstetrician must feel that the state of nutrition and general well-being of the young infant is, to a great extent, dependent on the vigilance he devotes to it, and to the time and care he dedicates to the establishment and maintenance of breast feeding Only then does he fulfil the obligation he assumed when he consented to care for the mother during parturition

Jacobi stated, many years ago, that 85 per cent of deaths under 1 year of age occur in the bottle-fed infant If this is still true, a further lessening of our infant mortality depends largely on feeding the infant at the breast during the greater part of the first year of life

TABLE 1—LENGTH OF TIME OF BREAST FEEDING IN 1 000 CASES

Weeks				Months								
0	1	2	3	1	2	3	4	5	6	7	8	9
	139											
48	41	24	26	67	74	90	62	41	71	52	103	299
89				370							402	

This can be accomplished only if we have the wholehearted cooperation of the obstetrician I shall allow you to judge for yourself, after I have presented my figures, whether breast feeding is given the time and attention on the part of the obstetrician that I ask for it

REVIEW OF CASES

The review of these cases will be discussed under five headings

1 *How Long Was the Infant Breast Fed?*—We are confronted with the startling fact, as shown in Table 1, that 370, or 37 per cent, of these infants were nursed at the breast three months or less Against this, we have 402, or 40 per cent, who were nursed eight months or more Going a little more into detail, ninety mothers stated that they nursed their offspring less than one week In other words, 9 per cent of these mothers were allowed to or at least did deprive their children of their natural food within eight days of birth Ablactation was allowed in 139 nurslings before they were 4 weeks old Surely this does not speak well for the many efforts put forth in past years to encourage breast feeding

During these early periods, the patients, we must assume, were still under the observation of the obstetrician Undoubtedly, a large number of these mothers, if they had had the proper medical and moral support on the part of the obstetrician, could have nursed their offspring Furthermore, this is the period during which the breast milk supply often is not established to its full extent, and the mother requires advice and often encouragement from her medical adviser to overcome temporary difficulties At this time, the obstetrician must practice both the science and the art of medicine, must give of his time and patience, and must be alert to counteract ill advice from outside sources

2 *Was an Attempt Made to Estimate Quantity of Milk and, If Deficient, Were Complemental Feedings Resorted To?*—In only eighty-four cases of this series were complemental feedings advised and given Practically all others stated that the child was weaned without an effort being made to estimate the quantity of breast milk Of the eighty-four infants, 75 per cent were put on complemental feedings by me This would tend to show that the practice of determining the amount of breast milk and the use of complementary

---

*Read before the Section on Diseases of Children at the Seventy Third Annual Session of the American Medical Association St Louis May 1922

feedings is rarely resorted to by the obstetrician Yet it is a simple procedure, being far more practical and accurate than the milk analysis which is frequently given as the cause for weaning I was interested also in the length of time that a child was kept at the breast after complemental feedings were established A summary of eighty-four cases is presented in Table 2

The belief that insufficient gain, restlessness, curds in the stool, etc, are due to poor quality of milk is still far too common Insufficient milk is more often at fault than the quality of the milk Complemental feeding can be carried on for months, and, during this time, the infant, in many instances, receives 30 to 75 per cent of its food in the form of breast milk This condition obviously is preferable to bottle feeding The argument is advanced that accurate scales are expensive and that weighing a child before and after feeding is irksome to the mother Scales can be rented in all large cities and are less expensive than the price paid for milk over a period of months Again, it is not at all necessary to weigh the child before and after each feeding, checking up the amounts once or twice a week and striking an average is sufficient

3 *If Supplemental Feedings Were Given, How Long Was the Child at the Breast After Feedings Were Started?*—Here we included those cases in

TABLE 2—LENGTH OF TIME BEFORE WEANING AFTER COMPLEMENTAL FOOD WAS GIVEN (EIGHTY FOUR CASES)

Weeks			Months							
1	2	3	1	2	3	4	5	6	7	8
0	1	0	4	13	22	14	22	4	3	1
5										

which two or more bottles were substituted for breast feedings In eighty-three cases, we have definite information that this was done with the idea of keeping the baby at the breast and not with the idea of weaning it Many times we were told that the physician explained to the mother that by following this procedure and nursing the child two or three times in twenty-four hours, or often only at night and in the morning, the breasts would fill up This is a striking example of the fact that these men did not comprehend that only regular, thorough emptying of the breasts will maintain a milk supply and that any other course must quickly lead to bottle feeding The length of time elapsing between the institution of supplemental feedings and complete weaning bears this out and the figures as presented in Table 3 are in marked contrast to the figures on complemental feedings

I am not unmindful of the fact that a mother who cares for her children and her home has many duties Therefore, in cases in which the milk supply is well established, I believe that one bottle feeding may be given after the third or fourth month We must use our judgment, as some mothers will take advantage of this privilege and gradually wean the child, while other mothers are actually benefited by this break in the daily routine We do not sanction the use of the bottle in early infancy When two or more bottles are given, weaning is not far off

4 *What Food Was First Given the Child on Weaning?*—In answer to this question, we were agreeably surprised to note the result of the propaganda for pure cow's milk as the best food for the young infant In 720 cases, or 72 per cent, the infant was given a modified cow's milk without the addition of a proprietary food The remaining 270 infants were fed as follows Eagle brand, 105, goat's milk, 36, Nestles, 6, peptogenic, 2, malt soup, 1, Sunbright, 1, Dennos 8, condensed milk, 9, milk and Eskay's, 27, milk and Mellin's, 42, malted milk, 29, Dryco, 9, Klim, 1, Allenbury's, 2, Mammala, 2 If we add the cases in which the infants were fed on goat's milk to the 720

TABLE 3—TIME BETWEEN INSTITUTION OF SUPPLEMENTAL FEEDING AND WEANING (EIGHTY THREE CASES)

Weeks			Months

62							

in which they were fed on modified cow's milk, we are gratified to find that 756 children were started on milk without proprietary foods Having been able to educate the laity and profession to the use of modified cow's milk, we should also be able to attain similar results from an intensive campaign in regard to the establishment and maintenance of breast milk

5 *Reasons for Weaning*—The reason for weaning was ascertained in 337 of the 371 cases in which the infants were weaned during the first three months In almost every instance, the physician was consulted and knew that the child was to be weaned Fifty different reasons were considered valid excuses for depriving these children of breast milk Of these fifty reasons, we cannot possibly consider more than nine as justifying such a serious step These reasons are death of mother, pregnancy, adoption of child, some cases of abscess of breast, tuberculosis, acute illness of mother,

TABLE 4—REASONS GIVEN FOR WEANING

1	Death of mother	6	29	Cracked nipples	6
2	Cesarean section	3	30	Milk dried up	18
3	Insufficient milk	69	31	Vomiting	6
4	Inverted nipples	5	32	Menopause	1

23	Convulsion of child	1			
24	Acid milk	2			
25	Child would not nurse	5			
26	Pregnancy	4			
27	Milk too rich	2			
28	Baby not strong enough to nurse breast	3			

severe operation on mother, mother had to work, and toxemia of mother Only sixty-four cases, however, came under these headings, and of these thirty-five are doubtful, since they were due to abscess of breast and acute illness of mother Among the acute illnesses of the mother, we find the following herpes

zoster, asthma, influenza, malaria, eczema, fever, pyelitis, pyemia, quinin poisoning, valvular disease, septicemia, infected finger, tonsillitis, insanity and diabetes Some of these may or may not demand permanent weaning of the child

Of the 337 infants enumerated, a total of ninety-five were weaned because of insufficient milk or insufficient gain These two reasons were recorded in more than twenty infants before they were 1 week old The great majority of these ninety-five infants, with proper care and, if necessary, with complementary feeding, could have been entirely or at least partially breast fed Curds in the stool, convulsions, pertussis, menstruation, cleft palate, spastic paralysis, prematurity, acid and salty milk, mother had not nursed previous children, etc, are reasons so ludicrous that we hesitate mentioning them except that they demonstrate the lack of a proper conception of the fundamentals of breast feeding A mass of literature has gone out to the public, but we believe that to accomplish results we must reach not only the public but also the profession The subject should be discussed more frequently in our medical societies and in our journals Pediatric societies, we believe, can do considerable good by issuing pamphlets on the subject and distributing them to physicians throughout the country The Southwestern Pediatric Society issued such a brochure last year and mailed a copy to every physician in southern California Breast feeding is a vital subject at least once to every human being Not so with appendicitis, yet the surgeons did not hesitate to speak or write on that subject unceasingly for years, until they had educated the laity and the entire medical profession to the correct point of view Let us follow their example, endeavoring to make each and every physician as ardent an advocate of breast feeding as he is of the surgical cure of appendicitis, with the full realization that, in advocating and carrying on breast feeding, he is practicing preventive medicine in the supreme sense of the word

Brockman Building

ABSTRACT OF DISCUSSION

DR ISAAC A ABT, Chicago Dr Dietrich has shown that 36 per cent of women nursed their babies at the breast three months or less, while 40 per cent nursed their babies eight months or more, that at nine months, 9 per cent nursed their babies less than one week, and that in 14 per cent the babies were weaned before the age of one month Dr Dietrich makes the correct distinction between supplemental and complemental feeding There is a great deal of confusion about those two words Complemental feeding is the type in which the baby is given the bottle immediately after the nursing, while supplemental feeding is that type in which a bottle is substituted for nursing I am in full agreement with the expressed opinion about the stools of breast-fed babies A slight apparent abnormality in the stools of a breast-fed baby is not of equal significance to that in a bottle-fed baby After the breasts are functioning properly, it is justifiable to give a supplemental bottle after the baby is 3 months old If supplemental feedings are begun before the third month, the necessary stimulation to the breast is not supplied After the third or fourth month, the baby frequently needs additional food I believe with Dr Dietrich that when two or more bottles are given early in lactation, weaning is not far off In the literature one frequently notices the statement that tuberculosis is the one absolute indication for weaning I think, however, that the reasons expressed in the paper may be accepted The point we should make is that every baby should be nursed at the breast unless the mother is incapacitated by acute disease or by some mental disturbance or social condition which necessitates her leaving the baby

DR WILLIAM A MULHERIN, Augusta, Ga In the South and in the West there is more maternal feeding than in the East and in the North The reason for this is that Southern and Western physicians are convinced that mothers can nurse their babies I belong to the Ross Snyder-Sedgwick school In 1906, Ross Snyder called attention to the fact that there was too little breast-feeding and that we were drifting too far from nature Sedgwick gave the modus operandi There are five essentials which will succeed with maternal feeding (1) conviction on the part of the physician that mothers can nurse their babies, that breasts are intended not for ornament but to nurse babies, (2) conviction on the part of the mother that she can and will nurse her baby, (3) stimulation of both breasts by nursing the baby at regular intervals, (4) emptying the breasts by manual manipulation after each nursing, and (5) patience and perseverance on the part of physician and mother From actual practice, I feel convinced of two facts 1 Nearly every mother can nurse her baby at the breast, if properly encouraged 2 Nearly every mother's milk agrees with her baby I know of no single factor or several factors operating today in the interest of babies' welfare that will save more babies' lives than the general adoption of maternal feeding

DR T C MCCLEAVE, Oakland, Calif Physicians all know, from experience that the responsibility for the condition of affairs Dr Dietrich described lies primarily with the man who brings the baby into the world What Dr Dietrich described as relating to his practice is certainly true in our community I have in mind one obstetric institution in which babies invariably are fed malted milk as prescribed by the head nurse Babies are as a routine taken off the breast, and that institution does not stand alone in this practice The use of the terms complemental feeding and supplemental feeding has been confusing to a great many people The word supplemental" does not describe the use of a bottle instead of the breast The proper term is 'substitute feeding" Complemental feeding is a correct term Two years ago physicians believed that the more food we gave to the mother, the more milk she would give, but a physician in Detroit described careful observations on the feeding of mothers and declared that it was unnecessary to stuff a mother to enable her to breast-feed the baby The second point is the longer nursing interval Out in the West, babies are generally nursed on a four-hour schedule right after birth A few babies do better on a three-hour schedule for a while, but the four-hour schedule is immediately taken up It does better for the mother, as she can go out to social functions, and have a comfortable day with five feedings, she sleeps all night and the whole family is contented

DR M L TURNER, Des Moines, Iowa There are a number of reasons why the mother may not be able to nurse the baby First of all, we should teach the mother how to live before the baby is born so that when the baby comes she does not need to change her diet Neighbors should not be allowed to bring in delicacies and impair her appetite Let the mother eat wholesome meals before as well as after the baby is born, and she does not need to stuff herself in order to have plenty of milk for the baby Another important point in successful nursing is to have the baby put to the breast immediately after it is born There is a substance in the mother's breast which is essential for the child A dram of colostrum is worth a quart of water at this period And I endorse Dr Mulherin's suggestion for emptying the breasts I insist that the mother nurse both breasts every time she nurses the baby Every mother can nurse her baby I have been able to establish the milk in the breasts of twenty-five mothers during the last two years from two to eight weeks after they have weaned their babies, and in one case after three months One mother was 39 when her first baby was born The baby had been weaned for eight weeks and was put back on the breast She was able to nurse the baby for a year I think, as Dr McCleave says, that we are confused in the terms complemental and supplemental feeding I

agree to the term "substitute feeding" I do not agree with Dr Abt that after the fourth month we should give the baby a substitute feeding Any time the breasts are not stimulated regularly, they fail to secrete The mother can nurse the baby every four hours, and can then go out and have her afternoon tea and have enough milk to keep the baby nursing

DR L R DEBUYS, New Orleans This paper emphasizes the necessity of the proper care of the infant immediately after birth It would have been interesting if he had told us what advice had been given these mothers as to the care of their babies Were they delivered by obstetricians or otherwise, and who gave the advice which they followed? Pediatricians should fight for the proper care of the baby immediately after it is born, and this advice should be given by those adequately prepared to give it

DR ADA E SCHWEITZER, Indianapolis We have been engaged in the study of the feeding of 5 336 children aged from 8 weeks to 6 years We compared relative height and weight of Indiana children Fourteen in every hundred were below the standard weight for height An inquiry into the feeding of these children showed that 65 per cent of the children of the underweight class had not been breast-fed, only 11 per cent of the underweight class had been breast-fed exclusively in early life The prevalence of breast feeding in infancy is shown by the fact that about 72 per cent of the children studied had been breast-fed all the way from six weeks to six months This, we felt, was a fairly good showing as these studies were made outside the larger towns, largely in the rural districts The percentage of breast feeding in any community seemed to depend on the advice given by the physician to the mother concerning its advisability In addition to the reasons given by the author, early weaning among these Indiana mothers often was resorted to because the baby cried a great deal, or because he did not seem to be satisfied We found that among infants who were breast-fed exclusively and among the infants on a supplemental feeding, a high percentage were up to standard height and weight We also found that babies fed proprietary foods furnished the highest percentage of underweights Of the older children those on a varied diet were up to standard, but in the country districts, where the children were given a diet of meat and potatoes with not enough of leafy vegetables and not enough milk the percentage of underweights was higher Although we were unable to check up the condition of the children as often as was desirable, we felt that this was an interesting study We did show to the people of Indiana that the highest percentage of poorly nourished children occurred in the group who were not properly fed early in life

DR G A WARREN, Black Rock Ark Eleven years ago Dr Jacobi said that a most significant emblem of one of the artificial foods was the picture of an angel because if you feed babies this food, they would soon become angels He emphasized the value of giving cow's milk if the mother's milk was not sufficient We should all be impressed with the importance of breast feeding I think that a child should be nursed until it is 18 months of age There ought to be two periods for weaning a child A child ought not to be weaned during the hot months without some of the reasons given by the author I do not believe that nature intended that a child should be put on foods until it has at least sixteen teeth and that is usually in the second year

DR. EDGAR A HINES Seneca S C The keynote of the proposition, as I see it is how to reach the medical profession of America Under the inspiration of the vice chairman of this section, we are organizing state pediatric societies in the Southern states Ten of our states have been so organized One of the main objects of the organization is to give the profession just such information as has been brought out by the author and by those who have discussed his paper At the next meeting of the South Carolina Medical Association the chief place on the program will be given to the discussion of breast feeding and that may be done throughout these ten Southern states I believe that within two years the entire sixteen Southern states will be organized in that way

DR CLIFFORD G GRULEE, Chicago The paper gives a very good outlook on the reasons which we may expect for weaning children That is very important, and it shows very clearly that in the vast majority of cases the reasons for weaning children are entirely inadequate It calls attention to the fact that the new-born period is very important In my opinion the introduction of breast feeding in the new-born is the crux of the situation If one does not get these babies to nurse during the first few weeks of life, one does not get them to nurse at all It usually rests with the obstetrician whether the baby nurses or not A lot has been said about the mother nursing the child, and nothing was said about the child nursing the mother I have had charge of the babies in the maternity wards of a general hospital, and I find that the baby's tendency to sleep is the one factor that takes it away from the feeding If we keep them awake and at the breast and force them to nurse, they will do well If these babies nurse a few minutes they often go to sleep They have to be stimulated and kept awake and made to nurse

DR GEORGE E BAXTER, Chicago It is important to emphasize the most common conditions which we meet For example, it has been my habit to ask the question of every mother what reason she had for weaning the baby Our percentages run much higher than Dr Dietrich's for the following two or three reasons for weaning, which are found in his tables 'insufficient milk' 'trouble with the stools," "advice of physician or nurse' I would like to emphasize one point which Dr Abt stressed, and that is the condition of the stools We would have far more babies nursing at the breast if the physician, nurse and mother never looked at the stools A green color, a few curds, a little mucus in the breast-fed baby stool has been misinterpreted, and consequently innumerable infants have been deprived of their best and safest food All pediatricians know this, but very few of them stress the importance to obstetrician and general practitioner Another factor is the time of nursing Dr Grulee has mentioned the fact that these babies go to sleep on the breast We should be careful that the nurse and mother understand that nursing at the breast means sucking at the breast We must determine whether the baby is getting any milk Weighing before and after nursing is a good thing for a few times only It is irksome to the mother and baby to keep it up as a daily and regular habit at each nursing period and no baby will get the same amount from each breast at each nursing period By careful observation, the mother will soon learn whether the baby is actually sucking and swallowing or sleeping or nibbling using the breast nipple only as a pacifier I firmly believe that the usual time which is practiced in all hospitals of having the baby nurse for twenty minutes is fundamentally wrong, because no two infants will get the same amount of milk from the breasts in the same given length of time We should pay more attention to the way the baby sucks and swallows Teach the mother and nurse to observe whether the baby is actually sucking and swallowing The old and less elegant word 'suck' expresses far more accurately the action of the baby at the breast than 'nursing" Instead of having the baby suck ten minutes on one breast and ten minutes on the other, we should have the baby suck until he gets all he can or wants for these infants have an intuitive sense if you please of how much they need I am getting to the point at which I advise mothers to turn the clocks to the wall when they are suckling their babies

DR HENRY DIETRICH, Los Angeles I think that Dr McCleave's idea in regard to the use of the term "supplemental' feeding is an excellent one, and that by using the term substitute feeding we may prevent some mothers from starting the babies on the road to weaning We can learn a great deal from the dairyman If we spend some time with the dairyman we will get some important points that will help us in the better understanding of the establishment of breast milk In answer to Dr DeBuys' question some of these children were under the care of expert obstetricians, a great many were under the care of general practitioners One infant that was given no breast milk was the daughter of a patient who found it necessary to have an obstetrician

come from New York to Los Angeles to confine her and also to have her take the baby from the breast Both Dr DeBuys and Dr Grulee are correct in regard to the new-born period I agree that that is the time when these babies need the most attention There are many young infants who from the time they are born are left to the care of the nurse The mother is stuffed with whatever the nurse gives her, and if the mother does not have a plentiful supply by the fourth day, the baby is put on the bottle And this holds true in as large a city as Los Angeles, where in some instances the physician never saw the baby from the time it was born until the mother left the hospital

POLITICS AND THE HEALTH OFFICER*

MATTHIAS NICOLL, JR, M D
Deputy Commissioner of Health State of New York
NEW YORK

There can be no question that public health service as a career does not offer sufficient attraction to many of the best type of technically trained men, whether they are physicians, sanitary engineers or statisticians, to induce them to make it their life work Although, in recent years, such men are entering the service in greater numbers than formerly, the need for thoroughly competent officials by states, counties and cities is far greater than the supply, and, it may be added, greater than the demand

The reasons for this unpopularity of public health service are

1 Lack of knowledge on the part of many graduates of the professional schools as to the character of the work, the opportunities afforded for developing it and the qualifications, technical and personal, which are essential to success In order to furnish this information, it would seem desirable to introduce somewhere in the curriculum of medical and allied professional schools, including schools of nursing, a course of lectures, delivered by an experienced and successful health official which would serve to impart exact information as to the opportunities offered by public health service, and to bring out facts as to the past, present and probable future of the work, its advantages as well as its disadvantages compared with private practice It is very certain that the entrance into this field by persons who have little or no knowledge as to what is before them must, in many cases, inevitably lead to disappointment and unrealized hopes, and that many potentially able health officers are lost to the service because they have not been informed as to its opportunities and advantages

2 Inadequacy of compensation It may be stated, as a general rule, that salaried public service of an administrative and technical nature, in this country, if it be honestly and efficiently performed, is not adequately compensated Public health service is by no means the least conspicuous example It is hardly to be expected that communities, even the most populous and wealthy, will be willing and able to pay salaries to health officials which will compare with the income which many technically trained professional men command in private practice and in some industrial corporations But that the salaries paid should represent a reasonable return on the capital invested in money and the time devoted to preparation, and should afford a decent living, with something saved, to those who have no other source of income, is beyond dispute

The full-time health official, and even he who honestly devotes part time to the duties of his office, becomes, year by year, less able to earn a reasonable living in private practice Health service is, for many reasons, incompatible with private practice and is usually destructive of the desire to enter or return to it, so that it not infrequently happens that, after years of such service, the health official, having relinquished or been relieved of his office for one reason or another, finds himself without means of support, and a seeker for any work which will enable him to live The lawyer and business man who temporarily neglect their private work for public office have something to fall back on Indeed, it not infrequently happens that their professional and business returns are enhanced rather than diminished, for there is no incompatibility between private and public work of this character, such as exists between official and private medical work This is a matter which state, city and county officials do not realize, and will not realize until they are taught the value to the community of efficient health work, and that such work must be reasonably paid for or dispensed with While the pay of health officials has notably improved during the last few years, it is by no means generally adequate, and, until it becomes so, many of the best men cannot afford to enter the field of public health

3 Uncertainty as to tenure of office Quite as important if not more so than the foregoing as a deterrent to entrance on public health work is the uncertainty of tenure of office Many qualified men, especially those with some private means, would, notwithstanding the meager financial returns, enter into public health service, on account of their liking for it, were it not for the fact that they have little or no assurance that even if they perform their duties satisfactorily and obtain results, they may not be thrown out of office, for political or personal reasons, and with no opportunity to protest

The majority of adult Americans of intelligence have political opinions and more or less strong party affiliations, and it would be unfortunate for the country if such were not the case But there is a class of politicians which exists in all parts of the country which could be well dispensed with, namely, those who are willing to sacrifice the welfare of a community to an assumed political advantage, in order to satisfy a personal or political grudge or to bestow political favors Health officers, through no fault of their own, all too often fall victims to the activities of this shortsighted, mistaken policy, and the community is thereby deprived of valuable and faithful service

It will be conceded that the politics of a health official should be of no more concern to a community than the politics of the family physician to an individual There is no defense for partisan interference in the work of an official who is devoting his service to the health and lives of the people of a community, except ignorance of the value and importance of such service, and it is this ignorance, by which the health officer suffers, for which he is very often himself largely responsible, in that he has failed to impress on the people of the community, including those with political power, the value of services rendered In other words, he is regarded by the latter as any other office holder, and is subject to the same rules of the political game A

* Read before the Section on Preventive and Industrial Medicine and Public Health at the Seventy Third Annual Session of the American Medical Association St. Louis May 1922

health officer who has accomplished such results as to enlist the support and backing of the general public in his community is fairly secure in his position The politician who brings about the removal of such an officer, replacing him by an incompetent, is liable to receive from the people, at the first opportunity, his justly merited reward There is no greater asset in any administration than well-conducted health work, and no other work comes nearer to the heart of the people or so generally enlists public cooperation This fact is being recognized more and more clearly by governors, mayors, commissioners and minor administrative officials If it be granted that health officials should be free from political interference, it is equally true that they themselves should perform their duties without regard to political or personal influence and that they should on no account take part or use the prestige of their office in any partisan campaign Wherever their sympathy lies, in their official acts they should remain absolutely neutral The health officer who openly or privately works for the advancement of one political party or another is entitled to no sympathy if, as a result, he loses his office He has played a game, lost it, and should pay—on demand

Health officials should work in as close harmony as possible with the administration, and cooperate in making it a success They should remember that the technical knowledge pertaining to public health work and its importance to the community is not often possessed by coordinate lay officials and when differences of opinions arise as to policy relating to health administration, they should make every endeavor to render clear their position and reasons for acts, the value and desirability of which are being questioned, often through lack of understanding Tactlessness, arrogance and too great readiness to attribute evil motives to those with whom officially and unofficially they come into contact are just as certain indications of unfitness for public health service as subservience and eagerness to curry favor at the sacrifice of plain duty However technically qualified by education and experience, the health officer, if constantly at odds with the administration, will be able to accomplish little or nothing, and his services to the community will be of very little value If this lack of amicable relationship is due purely to political or personal motives on the part of members of the administration and to no fault of his own, his work having met the approval of the people of the community, the health officer may, in most cases, rely on public support, which is exceedingly difficult to overcome If, on the other hand, it is a question of incompatibility of temperament, or the health officer is suspected or known to be playing politics, it is better for him and the community that he should resign

What may be done to make more secure the tenure of office of efficient health officers? Civil service, while theoretically valuable for this purpose, has not, in effect, proved much of a deterrent against unjust removal from office The state department of health of New York through the public health council, and in cooperation with the state legislature and conference of mayors, has taken certain steps which should prove of value in remedying this evil, first, by an act of the public health council, July 6, 1915, in establishing qualifications for local health officers, except those of the first and second class cities Under this regulation, candidates for health officerships are obliged to qualify themselves by taking a public health course outlined and supervised by the state department of health in cooperation with one of the medical schools of the state, or, in lieu of such course, to furnish to the council evidence of education and training in public health which shall represent an equivalent of the work required by the course Although handicapped by the war and two great epidemics up to the present time about 600 health officers out of 969 have either taken this course or otherwise qualified, and about 150 are now registered in it This regulation has served to prevent the appointment of men who were not qualified to hold office, and to educate the appointing power in the various communities as to the necessity for choosing men with some training in public health, and not those, however respectable, who are simply medical practitioners and without knowledge of public health matters In the majority of cases, it has rendered it difficult for such appointing power to displace the health officer whose qualifications had been approved

In 1921, at the instance of the conference of mayors and the state department of health, a law was passed, permissive in character, by which second and third class cities may abolish boards of health, and empower the mayor or city commissioner to appoint the health officer, who, however, must be qualified under the regulations of the public health council It makes the health officer responsible for the conduct of his office solely to the mayor or other appointive power, and not to an intermediary lay official, such as a public safety commissioner The term of the health officer was fixed at four years, but he could be removed without specific charges The latter provision obviously constituted a weakness in the law This was remedied at the last session of the legislature, which made the health officer removable on charges only after a public hearing A number of cities have accepted this law, and more contemplate doing so Furthermore, the newer city charters include identical provisions These two measures, I believe, should be regarded as a step in the right direction, but only a step City and county health officers (certainly those who give full time to these positions) should have a life tenure of office, unless sooner removed for cause, and, until the salaries granted are more liberal than at present, some provision should be made for a pension after retirement

It is quite obvious that causes for discontinuing the services of a health officer should include inability to achieve results after a reasonable period of trial, for I think it will be readily granted that, however well qualified a man may be in theory, when it comes to actual experience he may prove to be far from a success and communities should not be powerless by law to rid themselves of a health officer of this kind

It is perhaps too much to expect that in the near future adequately paid, well qualified, whole-time health officers, with a secure tenure of office, will be the rule rather than the rare exception This state of affairs can be brought about by one means alone general education of the public regarding the meaning and importance of efficient health administration

---

ABSTRACT OF DISCUSSION

DR A T MCCORMACK, Louisville, Ky There is not a statement in the paper with which I disagree and that makes it extremely difficult to say much except in repetition It has always seemed strange why after forty years the physicians of the United States have not realized the possibility of such an organization as will entitle them to such public confidence that the standards suggested in Dr Nicoll's paper

would be accepted by the public and the profession today It is impossible for the mayor to know a good health officer He may appoint a good health officer I do not mean he cannot do that because it has been done occasionally It does not necessarily happen that he is a good health officer because he is the family physician or political supporter of the mayor, and too frequently health officers are appointed for that reason If the appointments of health officers were made by law under the endorsement of the medical profession, which, after all, should be responsible for the public health of the state, with the provision that they must handle the financial affairs of the organization economically, the results would be better That provides sufficient continuity to make the proposition attractive even though the remuneration is small, not because the health officer should not receive a greater remuneration but because he has such an opportunity for good service that he feels compensated out of proportion to the amount of money he receives

DR VICTOR C VAUGHAN Washington, D C I agree with all that Dr Nicoll has said It has been my fortune to be in public health work for many years, and I think that, on the whole, Dr Nicoll is right in advising the health worker to steer as far as possible from active participation in politics In Michigan, where my health work has been done, I have generally been known as a Democrat, and at times have taken a rather prominent part in state conventions of this party During this time, or at least during the greater part of it, the state has been overwhelmingly Republican I do not believe that my political belief or my political affiliation has in any way interfered with my health work My most successful work along health lines has been carried out in legislatures in which my party had but few representatives Of course, a tactful man and a health official must be tactful will always be courteous, especially to his opponents I do not attach as much opprobrium to the word 'politician" as some persons do The politician is the man who persuades his fellow citizens to vote this way or that, and if he persuades them to do that which is for the benefit of the whole, I am quite sure that he is accomplishing a desirable work In my opinion, epidemiology is not studied with deserved thoroughness in this country at this time It seems to be a general opinion among medical men and nonmedical health workers that bacteriology and epidemiology are synonymous This is far from being true Epidemiology is the much broader term, the much older science and the one about which I believe less is known now than was the case a hundred years or more ago When pestilence was more frequent, the words 'loimology' and "loimography" were in general use, both by the medical profession and by the learned laity Loimology was defined in the old dictionaries as the sum of human knowledge concerning pestilence and the epidemiology of many diseases was quite extensively known long before the science of bacteriology came into existence

DR J A HAYNE, Columbia, S C In South Carolina we embody most of the recommendations that have been laid down in the papers read today When many of the states of the Union were wildernesses, the state of South Carolina made its medical profession the state board of health of South Carolina, and made it so by law To get the best out of the medical profession in other states it should be made the state board of health Then there will be an ideal board of health The state board of health of South Carolina has survived since 1879 This has been due to the intelligence of her health officers

DR MATTHIAS NICOLL, JR, Albany, N Y I trust that no one will conclude from what I have said that we in New York state are wholly lacking in political judgment I do insist, however, that conditions are different with us than in the state from which Dr Vaughan comes where one party is always in power while in New York state there is a change in administration every few years I would not give a penny for the health official who is not a politician in the sense of using political judgment in putting his own work across If he cannot do that he is lacking as an administrator Dr Vaughan, a Democrat, was a health officer in a Republican state, and no Democrat or Republican dared to remove him, but I contend that it is unnecessary and dangerous for a health official to mix in partisan politics He should confine his political activities to the conduct of his own office, in other words, attend strictly to his own business By so doing, and always provided his work meets the approval of the general public, he will usually be safe from political interference If, on the other hand, he uses his office for partisan purposes he will suffer the inevitable consequences sooner or later and have only himself to blame.

CONTRIBUTION OF STUDENT HEALTH SERVICES TO PUBLIC HEALTH*

J HOWARD BEARD, M D
URBANA, ILL.

A health service is neither an institution of philanthropy nor an organization for the promotion of paternalism It strives to cooperate, not to compete, with the medical profession It augments rather than decreases the practice of local physicians It has nothing to do with either compulsory health insurance or contract practice

It functions solely in the interest of sound economy by keeping the maximum number of students in the classroom and by insuring the investment in education by teaching elementary knowledge of the human machine, which each student must handle for the remainder of his life It endeavors to keep the normal fit, to restore the ill quickly to health

Health, as defined by it, is not merely the absence of disease, but the sustained striving for physical, mental, and moral perfection—constructive, dynamic living in the best environment that modern science is capable of producing Its purpose is to bring to the student, and through him to his community, the principles of hygiene and sanitation, as they pertain to him, to his home and to his vocation

Instruction to produce the necessary education—to promote this essential cooperation in making sanitary improvement more nearly commensurate with sanitary knowledge—must present a demonstration so clearly as to make the proper deduction inevitable Periodic physical examinations, personal conferences, physical education, sanitary inspection and didactic instruction offer this opportunity for a student health service to make a distinct contribution to public health

PHYSICAL EXAMINATIONS

A thorough physical examination benefits the student, the community and the medical profession It warns of dangerous conditions of which the student may not have been aware Persistent albuminurias, unsuspected heart lesions and unrecognized hernias are frequently found Their discovery and treatment mean a longer period of activity in those who, by special training and experience, are to be of great value to society Students with these abnormalities or with previously unrecognized astigmatism need little instruction or encouragement to become advocates of medical supervision of school children

The necessity of compulsory physical examination at registration is not always understood until a large percentage of those examined have been called for reexamination and advice concerning errors of refrac-

* Read before the Section on Preventive and Industrial Medicine and Public Health at the Seventy Third Annual Session of the American Medical Association St Louis May 1922

tion, carious teeth, flat feet, curvature of the spine, incorrect posture or other defects. Then the significance of the requirement becomes apparent, and students freely express their appreciation of the opportunity they have been given to ascertain their physical condition. Certification of physical health, as a prerequisite to entering athletics, and prescriptions for corrective gymnastics further emphasize the importance of physical examination. The establishment of a sympathetic attitude in the mind of the laity toward health measures is of the utmost importance, if public health is to attain its greatest advancement. While it is usually difficult to make those who think they are well show great interest in 'how to keep well," the sick and defective are easily interested in the fundamental principles of corrective and preventive medicine.

Unhappily, certain students must learn that their defects make it necessary for them to revise their plans as to courses to be pursued in the classroom and in physical education. Their misfortune will, to a considerable degree be compensated if they carry over into life an appreciation of the relation of physical and mental adaptation to successful careers and to efficiency in occupation.

In physical examinations, the students are required to undergo anthropometric measurements, and the observation of a dentist, an aurist, an oculist, a laryngologist, a clinician and a surgeon. They must also submit a specimen for urinalysis. A number have revealed to them, for the first time, the meaning of specialization in medicine, a discovery of value both to medical practice and to public health.

The findings of the physical examinations of a large number of recent graduates of public schools serve as an index of the efficiency of the departments of physical education and of medical supervision. If the health services of institutions of higher learning will adopt a "follow-back" as well as a "follow-up" system in dealing with defects of registrants, they will be able to cooperate with the schools from which the students come, to mutual advantage. The examination of many young men and women will be of great help in making generalizations of public health value. The facts obtained in such instances and the careful following of the graduates should lead to interesting observations concerning the cause of the so-called degenerative diseases and the influence of occupation and habits in relation to them.

Physical examinations and the conferences following them afford opportunities to release minds from the thraldom of imaginary ailments, from the evil of misdirected sympathy and from the introspection and depression created by charlatanism and quackery. Advice, encouragement and mental prophylaxis lead to the establishment of the proper attitude of mind, which is essential to the prevention of subsequent burdens on family and society.

CONFERENCES

A health service encourages the student to seek information whenever he thinks his health requires it. While this policy brings in trifling injuries and slight ailments, it leads to the discovery of potential or incipient conditions that need attention. The community is better protected against communicable disease, and the student avoids illness and infected wounds.

Conferences afford an opportunity to view the stress and strain of modern education on the central nervous system under varying conditions. They reveal the handicap of bad habits of study and of the wrong types of recreation. They bring to the surface the blight of worry, the far-reaching effects of unhappiness and depressing environment on cerebral efficiency. They present a chance to demonstrate the potency of psychotherapy, the benefits to be derived from the proper mixture of work, play, and social intercourse. They emphasize the wholesomeness of optimism.

Frequently these conferences deal with subjects not immediately affecting the student's health. He may ask for some data in connection with a hospital in which his father is interested. He may want plans for a sanitary outhouse for his country home, references to some form of public health work on which he is writing a long theme, or a list of text books suitable for the high school students to whom he will teach hygiene next year.

Former students frequently write letters or call for information concerning some phase of hygiene and sanitation in which they are particularly interested. On the day this article was written three letters arrived, one from a graduate in journalism, specializing in advertising, who requests data concerning tooth-paste. He wishes references to aid in adequately describing his product. A second asks for methods of destroying mosquitoes, while the third wishes to borrow a set of slides on 'school sanitation."

In many of these conferences, questions often arise which involve medical tradition or touch on problems of medical practice. They offer an opportunity to show the future community leaders that medicine is rapidly changing from an art to a science, based particularly on chemistry, physics and biology. Students must learn that results in medicine are not haphazard, but that cause and effect follow in logical sequence, as they do in experiments in the laboratory. There are still too many intelligent people who think medicine is a medley of tradition, mystery, long-sounding terms and personal opinions. In removing this false conception from the public mind, modern medicine has much to gain, nothing to lose.

EDUCATION

The great contribution of a health service to public health is the education of the student to appreciate the importance of hygiene and sanitation to himself and to his community. The mere introduction of an elementary course into the required curriculum of an institution of higher learning is not without significance to preventive medicine. Greater emphasis must be placed on the fact that dissemination of knowledge essential to self-preservation, is the first duty of education.

What the universities and colleges should do in the teaching of hygiene depends largely on the amount and nature of the instruction given in the grade and high schools from which their students come. For the present, the equivalent of three hours a week for one semester would not indicate an undue emphasis on hygiene. The time might well be divided, two thirds to general, and one third to vocational hygiene, the former to be required of all students during their first semester after matriculation, and the latter to be taught later, in connection with their professional training. The instruction should be both didactic and practical, and ample opportunity should be given for the students to confer with their instructors and with members of the health service staff.

Members of the staff of the health service, in their daily contact with students, have an excellent oppor-

tunity to give practical significance to the didactic and laboratory instruction in courses allied to medicine The student finds new interest in zoology or entomology when the relation of protozoa to dysentery or of insects to disease is discussed during a consultation for enteritis or malaria The overlapping of the problems of sociology and medicine are particularly attractive to the man or woman studying social evolution, charities, population or criminology The senior in the engineering school will exchange information with the sanitarian concerning the problems of Panama, the Rand or the Hudson Tunnel, with the keenest interest and to mutual benefit Even the tyro in chemistry, wrestling with the mysteries of affinity, is not immune to a simple statement of the principles of chemotherapy

The student's familiarity with the work of a health service has a high educational value Members of its staff should see that the student learns that the waiters dish-washers, cooks, dairymen and other food handlers employed by the university are examined physically, in order to exclude those with communicable diseases from handling food, and that they are vaccinated against smallpox and inoculated for typhoid fever, in order to protect the patrons of cafeterias from disease In institutions in which a considerable amount of student help is used, this lesson becomes very practical The requirements of the student officers' reserve corps and the advice of heads of departments of bacteriology and sanitary engineering that their students be vaccinated and inoculated further emphasize the importance of immunization

A case of diphtheria properly handled in a fraternity house will do more to demonstrate the value of antitoxin, the use of the Schick test, the danger from carriers and the necessity for isolation than several hours of didactic instruction It presents a demonstration whose significance remains throughout life It creates a respect for quarantine and promotes a spirit of cooperation in the prevention of disease

A health service greatly aids in the promotion of public welfare by the cultivation of an appreciative attitude toward hospitalization. Many of the most intelligent people have an unreasonable dread of hospitals, and use their facilities for diagnosis and treatment only as a last resort When students are encouraged to go to the infirmary early and conditions are such that they cannot very well be cared for at their lodging houses when sick, hospital treatment is expected It will mean much to public health to have our college graduates understand that they can obtain better care for themselves and for their families in a well-conducted hospital than at home What will this mean to maternal and infant welfare, to diagnosis, to treatment and to the equipment and maintenance of hospitals?

SANITATION

Environment is the best laboratory for instruction in sanitation By cooperation of the offices of the supervising architect, the superintendent of buildings and grounds and the health service, the necessary apparatus is provided for effective teaching The care of the campus, the style of buildings and variation in equipment, with their age, their methods of ventilation, heating and temperature control, means for provision and determination of humidity, lighting system, types of drinking fountains, sanitary plumbing, regulations for the care of the swimming pool, etc , are mute instructors, demonstrating the present conception of sanitation, and its evolution during the last few decades

If the school does not have dormitories, or they are so restricted as to require a large number of students to live in private lodging houses and to eat at such places as may be available, conditions arise that make a sanitary survey imperative Lunch counters spring up in unexpected places and pie-wagons vie with one another in seeking strategic locations with reference to student traffic As many students are compelled to live as economically as possible, they must patronize the cheaper places Proprietors of lodging and eating houses would show a lack of business ability if they did not give some attention to their financial returns

This combination of circumstances converts the student district into a community health unit, with all of its problems in the prevention of disease and the maintenance of health Here the health service operates, educating, creating public sentiment, encouraging and urging a demand for sanitary improvement It cooperates with the local boards of health, with public-spirited citizens and with the students, in helping to bring about the living conditions that make the college community one of the most attractive in which to live To interest a number of intelligent men and women in the sanitary improvement of their surroundings is to prepare them for better citizenship by their enlistment in the advancement of public health

Today, departments of health must teach by lectures, exhibits, pamphlets and propaganda, in order to produce the necessary education of the laity to overcome the resistance of ignorance and of short-sighted cupidity to the widest application of well-established methods to the promotion of public health They are compelled to give instruction that should be a part of the required courses of schools and colleges Unless the acorn of sanitation is planted in the schools, it will be many years before the oak can be used by departments of health in the erection of magnificent edifices of community and national health, commensurate with scientific knowledge In the sowing of the seed, a health service offers helpful cooperation with all organizations interested in the advancement of public health

A student health service and a school of hygiene are complements The first creates public sentiment and obtains moral and financial support for public health work The second trains experts for leadership and research The former strives to permeate the masses with elementary science as used in the promotion of health, the latter to produce torch-bearers and pioneers in preventive medicine

Is it too utopian to believe that the united efforts of the graduates of our institutions of higher learning, the staffs of departments of health the faculties of the schools of hygiene, and the medical profession are able to bring into existence those living conditions which are the goal of preventive medicine—the essence of applied Christianity?

ABSTRACT OF DISCUSSION

DR JOHN SUNDWALL, Ann Arbor Mich The third who failed to pass the normal tests for physical fitness as revealed by the draft examinations, the 80 per cent of our school-children who have defects that will make it difficult for them to make the proper social adjustments later on in life, the appalling number that must go onto the human scrap heap during that adult period of life when one should be enjoying to the maximum life and its various activities, and when one should be of the greatest economic and social value—these are responsible, in the very largest measure, for the tendency

of public health interests and activities to concentrate more and more on personal fitness or physical efficiency as one of its chief objectives No other institution offers better opportunities to develop this newer and broader conception of public health interests, health efficiency, than does the university Each student must be instilled with a profound appreciation of what physical efficiency means to his success and happiness and his value to society So saturated must the student become with the ideals and standards of health efficiency that he will feel that it is his moral, social and civil obligation to achieve and maintain a sound, active, vigorous, dextrous and harmoniously developed body In order to reach this objective—an appreciation of, and a desire for positive health on the part of the student—health efficiency should be made one of the basic divisions of university work The administrative officers and the faculty must become permeated with these ideals and standards The chief health officer of the university should sit in all the councils of the university s administration He should be given similar authority and dignity to that now ascribed to deans Furthermore, the university should require of all its entrants evidences of health and physical efficiency The thoroughgoing physical examination should be required of all entering students prior to registration These should be repeated annually Personal fitness and efficiency should be made a requirement for participation in the active life of the university The benefits, honors and awards of the university should be conditioned by the health and physical efficiency of the recipients Students should not be graduated who because of ignorance and neglect have allowed their body machines to run down" Assuredly the state is being cheated when the university underwrites physical defectives as capable of serving and directing society Let us develop a university type of physique It is precisely along these lines that the university can serve the public health movement best The university has the opportunity and possesses the facilities to attain these physical efficiency ideals Students later on in life become the leaders in their respective communities Thus these ideals and standards of health will radiate out into society

DR J HOWARD BEARD, Urbana, Ill I would like to emphasize what Dr Sundwall has said and to point out that a health service is an economic necessity

MALARIA CONTROL OPERATIONS IN RELATION TO THE ULTIMATE SUPPRESSION OF THE DISEASE*

C C BASS, MD
NEW ORLEANS

In his book on "The Prevention of Malaria," Sir Ronald Ross[1] shows by elaborate mathematical calculations, and in quite a convincing way, that sufficient reduction in the anopheline density in a given area would ultimately result in the complete disappearance of malaria from the area without the reduction necessarily being carried to total elimination of anopheles In other words, it is not necessary to secure 100 per cent of anopheline control to secure 100 per cent of control of transmission of malaria This is based on the small proportion of the total number of anophelines produced, which chance to live long enough, bite favorable gamete carriers and later bite other susceptible individuals In a large area, especially one not densely inhabited, there must be many thousands of anophelines produced, on an average, to one that actually transmits malaria He argues, therefore, that, if the anopheline density is reduced to below this theoretical point, malaria will ultimately disappear On the other hand, reduction of the number of carriers by curing the infection would not eliminate malaria entirely unless every infected person in the locality was disinfected and no others came in, provided, of course, that the anopheline density remained the same

This is based on the assumption (which I am bound to think is correct) that the anopheline density and malaria prevalence would be evenly distributed and that the reduction resulting from antimosquito operations or from treating the carriers would also be equally distributed over the area under consideration As a matter of fact, it seems to me that, in practice, the very opposite would probably be the case There is no reasonable probability that either antimosquito work or cure of carriers will be evenly effective over any very large area In any such large area, there would almost certainly be spots that had been overlooked or were insufficiently sanitated, where prolific breeding would continue, although breeding over the area generally had been reduced to below the necessary extent to permit transmission If such less well controlled spots were favorably located with reference to malaria carriers and susceptible persons, transmission would continue there and malaria would continue to be present indefinitely This would be the case, however effectively the other part of the area was controlled

The same thing is true with regard to control by curing carriers. Although all carriers in a small area, including a small group of people, may be cured of their infection, so that no further transmission will take place, no such thing can be hoped for when large areas, such as whole counties or states, are considered There will be some carriers not discovered, others may not be disinfected by the treatment taken, and others may refuse treatment If such carriers are favorably located for transmission with regard to anopheles breeding places and to other persons, transmission will occur and malaria will not disappear So far as I know, no intensive quinin control operation has been so successful in any large area as to eliminate all the carriers Therefore malaria has not been completely suppressed in this way, nor do I believe that it can be Neither do I know of any instance in which the disease has been completely suppressed in large areas by mosquito control operations carried out for the purpose of malaria control

However, there are many instances in which developments leading to mosquito control, often more or less incidentally, have led to total suppression of malaria over quite large areas I refer especially to the disappearance of malaria in this country during the past fifty or 100 years from large areas in New York, Pennsylvania Ohio, Michigan, Illinois, Missouri and other states This did not result from any intensive anti mosquito operations, nor from screening It resulted chiefly from the mosquito control that came from the clearing, drainage and other activities incidental to the march of civilization and the development of the country for agricultural and industrial purposes Much reduction had occurred, and, in fact the disease had disappeared from large areas before the mode of transmission was known and before wire screens were used to any considerable extent

During later years, use of screens, no doubt, whether intended for malaria control only or for other useful purposes as well, has hastened malaria elimination from

* From the Tulane University of Louisiana School of Medicine
* Read before the Section on Preventive and Industrial Medicine and Public Health at the Seventy Third Annual Session of the American Medical Association St Louis May 1922
1 Ross Ronald The Prevention of Malaria New York E P Dutton & Company 1910

the areas in which these natural developments were already bringing it about. Every transmission prevented by screens, which would otherwise occur, reduces the disease in the area to that extent and tends to hasten the time when there will be no more malaria.

No doubt cure of infected persons with quinin has also favored or hastened elimination of the disease from some of these regions by the developments incident to civilization and settlement of the country. Every person cured of his infection means just that much reduction of the chance of transmission.

While both of these things, screening or other antimosquito measures and the cure of infected persons, have contributed to the final suppression of malaria in some of these heavily infected regions, they have been contributing or, I may say, hastening factors only. The real cause has been development incident to civilization and settlement. Without this, malaria would not have disappeared.

What has occurred in this regard in England and in many European countries, and in these regions referred to in this country, is in progress over practically the entire malarious area in the United States. As the country is developed for agricultural and other industrial purposes, the prevalence of malaria slowly but surely declines. If we can look forward to a high state of development of the entire country, so also can we look forward to suppression of malaria, however much or little intensive malaria control work is done. At the present rate, it will be a long time until malaria has entirely disappeared. It will disappear, however, depending on whether, or when, settlement and development goes forward to the necessary extent.

The chief operations that bring about suppression of malaria are drainage and filling and clearing of the forests, not such as is done for the purpose of controlling malaria, but the much larger operations for settlement and development. The only permanent part of our present intensive malaria control operations is the permanent drainage and filling operations.

Since suppression of malaria inevitably results from the slow march of civilization and development, health agencies are interested chiefly in promoting such activities as will favor and hasten this result, especially those more or less temporary measures that lessen the prevalence of the disease during the period of more permanent development. This includes both antimosquito work and the proper treatment of infected persons with quinin. Each is useful, and they should generally go hand in hand. There are few instances in which antimosquito work would not be more effective in less time if combined with cure of the carriers. There are also few instances in which quinin control activities would not yield better results if combined with more or less mosquito control. The question is which is the more important and what proportion of attention should be given to each.

When considered from the standpoint of control of malaria in small areas, mosquito control has several decided advantages. The sanitation necessary tends to control other diseases and nuisances, while quinin does not do so.

When we compare the two measures from the broad standpoint of reaching the real malaria problem of this country, I believe that we must look to quinin as a most important factor. However much more desirable mosquito control may be, and however effective it may be in small areas, it must be practiced on a much larger scale than it has been in the past if it is really to effect the malaria prevalence over the whole country to any considerable extent.

Whether intensive mosquito control operations can ever have much influence on the big malaria problem of this country depends largely on the area that it is possible to reach in this way, compared with the area over which malaria prevails. Cost in money and man power and supervision or direction is a large item. In fact, this is one of the limiting factors. However certain the results might be, if the necessary resources cannot be obtained, the method cannot be applied.

Numerous demonstrations of malaria control by eliminating mosquitoes in small areas, chiefly towns and villages, have been made during recent years by the United States Public Health Service, the International Health Board and state boards of health. Many of these have yielded about as perfect results as could be asked for, constituting most convincing demonstrations of the effectiveness of sanitation.

I do not think the total area ever covered by intensive mosquito control work in this country, including the extracantonment zones during the war, would exceed 2,000 square miles (5,180 square kilometers). This is less than the area of three good sized counties. This is not more than one five-hundredth part of the total malaria infested area of the country. This emphasizes the fact that these operations have had little effect on the total malaria of the country, however completely malaria may have been controlled where they were conducted.

The cost of malaria control operations involving mosquito control by sanitation under experimental conditions or under such conditions as existed during the war does not serve as a suitable basis of cost. It costs much more under such conditions than when done under more favorable conditions.

A thing cannot be done unless the cost can be met. I refer to the cost not only in money, but also in other resources. I believe that those familiar with the most favorable of these successful operations must fail to see how the same operations can ever be applied to the entire malaria infected area of this country.

It must be recalled also that most of these operations have been carried out in towns and cities in which there is a more or less dense population and, by the way, where there is comparatively little malaria. The per capita cost, therefore, was comparatively low.

When we transfer mosquito control by similar intensive methods to the rural part of the country, where the malaria problem really exists, the per capita cost becomes much greater. In fact, it becomes so great that the extent to which such work can be done is certain to be limited. It cannot be done to an extent sufficient to affect seriously the total malaria prevalence.

The least expensive intensive mosquito control operations usually involve the expenditure of hundreds of dollars per square mile. An expenditure of even $100 a square mile would amount to an enormous sum if applied to the more than half a million square miles in the United States where malaria prevails. I do not question that it would be well-spent money. Nevertheless, it is money that would not otherwise be spent, and therefore represents new money.

Such antimosquito measures as screening homes also represents the expenditure of money that would otherwise not be spent. Do not misunderstand me. I most assuredly favor screening all homes where malaria prevails, as well as others. It would certainly cut

down the malaria rate tremendously, but it would be done at an enormous outlay of money for the purpose It does not matter whether antimosquito measures are carried out as a part of an intensive plan involving considerable effort and perhaps expenditure of money by the health agency behind it, or whether it is done by the people themselves as a result of publicity and educational work, it still represents an enormous outlay of money for prevention of disease that would otherwise not be spent It is true that it would still usually cost less than the disease it prevents

Let us now look, from the same standpoint, at the control of malaria by cure of infected persons with proper quinin treatment, to see whether it is likely to be correspondingly expensive and, as a result, equally difficult of application to the whole malarious region of the country People who have malaria may take proper quinin treatment to cure their infection, as a result of either intensive control operations which include this measure, or a general publicity resulting in making the supplies of standard quinin treatment available for those who need it, so that they will purchase it in place of other less effective remedies, or on the advice and directions of physicians who give their patients the proper treatment In either case, I feel sure the cost of the necessary quinin would be less than the average cost of the other remedies that would be purchased at the same time if the standard quinin treatment were not used If this is true, control by quinin involves only the expenditure for medicine of money that would be spent for other medicine No new money is required

Therefore, so far as cost is concerned, quinin is applicable to the whole malarious region of the country without cost, except for such publicity, propaganda or other activities as are necessary to get it done In this respect, quinin control has a decided advantage over mosquito control, which involves outlay of so much money that would not otherwise be spent For this reason, I believe quinin control is likely to prove a much greater factor in contributing to and hastening the suppression of malaria, in large areas or in the country as a whole, that inevitably results from development, than mosquito control operations undertaken for the purpose of controlling malaria or mosquitoes, so far as methods are known at the present time

If this opinion is correct, among the most important activities of health agencies interested in malaria control are those that lead to the provision of proper quinin treatment for persons who have malaria The rapidly increasing adoption of the standard quinin treatment by physicians and the growing use of it in place of the many less effective remedies offer much encouragement to workers in this field If this continues, it is reasonable to expect that it will hasten and contribute to the ultimate suppression of the disease in large areas in this country

SUMMARY

1 Malaria has disappeared from large areas in this country and in other parts of the world, chiefly as a result of development of the country, including drainage and clearing of the forest, incident to agricultural and other industrial pursuits

2 Malaria prevalence is slowly but surely decreasing over practically all of this country, as a result of the steady march of civilization and settlement of the country

3 This process may be aided and hastened by antimosquito measures or the proper use of quinin Health agencies are interested in encouraging these measures

4 The only part of our present malaria control activities that actually lead to ultimate suppression of the disease is permanent drainage and filling operations All others are temporary and must be continued indefinitely, or the tendency will be toward a return to former conditions

5 The cost of intensive antimosquito operations for malaria control is so great that they have not been applied to a sufficiently large part of the total malarious area of the country to effect seriously the total prevalence of the disease

6 The cost of such malaria control as results from infected persons taking proper quinin treatment does not involve any cost over the amount that would be spent for other remedies Therefore, it is applicable to the malaria problem of the country as a whole, and should be emphasized and encouraged by health agencies interested in malaria control

---

ABSTRACT OF DISCUSSION

DR L D FRICKS, Memphis, Tenn Dr Bass is one of a very small group who, having realized the importance of malaria to the South and its blighting influence on agricultural and industrial development, have fought for its control year after year I am in thorough accord with all that Dr Bass has said as to the importance of adequate quinin treatment in controlling malaria Certainly, malaria has been controlled in some localities by the use of quinin In a county of 25 000 population heavily infected with malaria, the U S Public Health Service, following the methods employed by Dr Bass in Mississippi, demonstrated that malaria could be enormously reduced by the general distribution of quinin in proper dosage The U S Public Health Service has approved the standard quinin treatment for malaria and recently has issued instructions that all patients in Public Health Service hospitals be given this treatment in preference to other methods of administering the drug, and advised that no malaria patient be discharged as cured immediately on the disappearance of active symptoms It should not be forgotten, however, that the U S Public Health Service has also demonstrated in many places that malaria can be controlled by drainage, that it has been frequently controlled by top feeding minnows, by proper screening or by oiling and that over large areas it has even disappeared in the wake of agricultural development without effort or deliberate intent on the part of the people concerned Knowing these facts, I cannot find myself in accord with any seeming reflection on any of the methods of malaria control just mentioned They all have their limitations and their uses but the malaria problem is so huge and local conditions are so varied that we must avail ourselves of all approved methods in stamping out this disease, relying more on one method in this community, more on another in that, and combining them all, if local conditions demand a combined attack I feel that too much importance has been attached by the advocates of each method of malaria control to the direct results obtained by them in their investigations or demonstrations This is only natural of course, but to my mind the educational value of a successful demonstration in malaria control is of far greater importance than any immediate result that can accrue in the United States for some years to come Education of the people and the fitting of malaria control into the permanent health program of the different state health departments are the big things to be done in the fight against malaria at the present time

DR M P RAVENEL Columbia Mo One point was not touched on, namely permanence of results, though Dr Bass did say that if the civilization of a country left it, as in the

case of the Roman Campagna, then malaria would return As I see the matter, it may be put thus Where drainage or filling is carried out, malaria is banished from that particular place for all time When malaria is controlled by quinin, it may clear up, but it will always spread from the borders of the cleared up district toward the interior The effect of quinin, in other words, is only temporary Drainage, filling, etc, are permanent measures, and in the consideration of the relative costs of any procedure, these points must always be borne in mind

DR ISAAC D RAWLINGS, Springfield, Ill There was a time when malaria was a very prevalent disease in northern and central Illinois It is said that in those days quinin was set on the table at mealtime with almost the same regularity during the malaria season as was the sugar bowl or salt and pepper shaker I recall vividly in Kansas in the early days how I and my brothers and sisters had to take 'that bitter stuff" and how the good mother kept track of the "chill day" of the individual members of our family It meant a bigger dose of quinin the night before and the morning of "chill day" As I recall the modus operandi of the "quininization" of those days I feel sure that many of us discontinued treatment too soon as relapses were frequent, but the very general use of the remedy in the various communities cannot be questioned I cannot escape the conviction that tile drainage, at least in northern Illinois and other Northern states, had more to do with the elimination of malaria and the permanent solution of our malaria problem than did the very general use of quinin Through the widespread educational propaganda advocated by Dr Bass, people can undoubtedly be persuaded to use quinin to a considerable extent, but education is not and cannot be made a "cure all" in malaria campaigns, for results are slow in achievement, owing to the relative indifference of the individual both as to his personal welfare and the best interest of his neighbor, even if he is intelligent and all the facts have been presented in the most convincing manner Education per se will not remedy the malaria situation, because the malaria carrier looms so large as an important factor and the difficulty of imparting the importance of the 'cure to completion" to the average lay mind is too great to give promise of the necessary high percentage of efficiency Many persons with all the facts presented discontinue treatment long before the eight weeks' prescribed course of treatment is completed The method advocated by the author is one of the most important of several methods of control, but experience has abundantly shown in many areas that the former swamps which are today the most habitable and desirable places to live in were made so by a combination of thorough treatment, elimination of the malaria carrier, drainage or filling in of swamps and pools where possible, substitution of larvicides for drainage or filling, removal of obstructing underbrush, use of 'top minnows', the screening of houses, and the control of water containers We may regard the control of malaria as a short chain consisting of the three links (1) infected persons, (2) anapholes mosquitoes (the connecting link) and (3) the noninfected person An aggressive attack on any one of these links in time, if 99 per cent effective, will solve the problem

DR S W WELCH, Montgomery, Ala The South has virtually admitted this malaria problem, and has gone about the task of getting the best methods possible to rid itself of the stigma of having a disease which is not common to other parts of the United States The U S Public Health Service and the International Health Board have come to the assistance of the state boards of the South, and state-wide malaria campaigns are now on The work is being carried on in a systematic way directed by Dr Fricks, whose headquarters are at Memphis All the Southern health officers and all the state boards of health have accepted the leadership of the U S Public Health Service in this work and we are actually eliminating malaria from the Southern states In my own state, Alabama, since 1917 the number of deaths from malaria has fallen from 530 in 1917 to 231 in 1921 There will be fewer deaths this year than there were last year This campaign is a vital organization, and we expect within ten years to show you the fairest country in the world entirely free from special health problems Large drainage projects are being promoted all over the South In 1916, top feeding minnows were put into the impounded waters of the Coosa River The state board of health has aided in the distribution of them, until now there is not a little branch that is not filled with these little fish which feed on the mosquitoes

DR W C WOODWARD, Chicago There is one aspect of malaria control we often overlook We are staggered by the enormous cost of filling and draining mosquito breeding lands because we view the matter only in the light of an annual appropriation We do not view such projects as we should, not from the standpoint of one year or even of five or ten years, but from the standpoint, as Dr Ravenel has pointed out, of all time If you cannot spend a million dollars this year for filling and draining, possibly you can spend a million dollars in the course of twenty-five years and in that way blot out malaria There is another financial point often overlooked, and that is the actual money return that drainage and reclamation projects bring through increasing the value not only of the land drained and reclaimed but also of land for considerable distances in all directions around It is only fair that those whose lands are benefited be assessed to the extent at least of the value to which their lands are enhanced by the improvement If we deduct from the cost of the average reclamation project the value of the land reclaimed and the amount of the enhancement of values of nearby property, I am quite sure that the cost of permanent abatement of mosquito breeding nuisances will be very much lower than appears at the first glance

DR C C BASS New Orleans Dr Fricks feels that perhaps the discussion is to some extent a reflection on the other methods of malaria control That is just as far as could possibly be from my intention He misunderstood me There is nobody who appreciates more than I do the absolute control of malaria that can be accomplished by mosquito control measures The point I wish to make is that the only method that is applicable to the malaria problem of the whole country at present is quinin control It can be brought about by publicity without cost except for the comparatively small cost of the publicity required On the other hand, any mosquito control undertaking for malaria control is too expensive to be applicable to a very large area I quite agree with those who have entered into the discussion that the only permanent malaria control that we are getting is the result of permanent drainage and filling operations Our temporary mosquito control and our quinin control are simply temporary measures which ultimately will lose their force if neglected or discontinued However, the work that is being brought about by the natural development of the country, and this intensive work in permanent filling and drainage operations, will finally bring about the desired results I wish also to point out that the disappearance of malaria from Illinois and Kansas, referred to by Dr Rawlings, was aided by the use of quinin, which no doubt hastened the process *The purpose of my paper was to emphasize* the idea that we ought further to encourage more extensive proper use of quinin and hasten the process of malaria reduction that is going on all over the country just as it has in these states Dr Welch pointed out that the malaria death rate in his own state had been reduced perhaps 50 per cent in four or five years That is probably largely due to the wide publicity that health officers and their assistants have given to the proper treatment of malaria I believe that quinin is one of the most important contributing factors in the reduction of the death rate from malaria that has occurred in his state and in most of the other Southern states during the last few years

---

Tobacco Angina Pectoris in Women—A recent editorial in the *Journal des Praticiens* of Paris states We have recently seen two young women with angina pectoris for which tobacco was responsible As the women were young and not syphilitic, they have apparently thrown off the disease"

THE MUTUAL INTEREST OF THE PROFESSION AND THE PUBLIC*

W S RANKIN, M D
Secretary, North Carolina State Board of Health
RALEIGH, N C

The profession and the public have a large mutual interest which unites them in a common task and draws them toward a single objective That interest consists of a surplusage of unnecessary, untreated and inadequately treated disease and impairment, which, in its totality, constitutes a waiting field of medical practice from two to five times greater than the present occupied field of medicine The last statement constitutes the major premise of this paper, and is so related to what follows as to make its assimilation by the digestive or analytic process advisable before other related matters are considered We turn, then, to a brief and rather general analysis of the unoccupied field of medicine

Beginning with maternity, we find from 25 to 35 per cent, say an average of 30 per cent, of the births of this country, a total of approximately 750,000 births a year, unattended by physicians These women pass through the valley of the shadow of death with no ray of the light of science to dispel its gloom, and with only the flickering candle of the midwife to guide them through their travail Add to the labors without medical attendance the enormous unsupplied need for medical supervision during pregnancy, add again need of the puerperal state for medical care so inadequately supplied, and you have an uncared for field of maternity from two to five times the size of that which is cared for

From infancy, we pass to childhood Add absent, delayed and inadequate medical attention to the cases of acute diseases of early life—measles, whooping cough, scarlet fever, diphtheria, meningitis, early manifestations of tuberculosis, etc—and add to that the needed treatment for the common defects of childhood (how significant the term), the 20 per cent or 4,000 000 public school children of the country with defective vision, the 75 or 80 per cent or 15,00,000 public school children whose mouths need treatment, in order to prevent subsequent digestive disturbances, rheumatism and cardiovascular damage, and the 5 per cent or 1,000,000 public school children who need operations for tonsils or adenoids, and again consider the relative sizes of the occupied or unoccupied fields of medicine
